ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Asst. Surg.-Gen. C. C. PIERCE, proceed to New York for conference with the executive committee of the State Health Officers' Association.

Sen. Surg. J. H. WHITE, proceed to Greenville, S. C., on temporary duty.

Surg. EDWARD FRANCIS, proceed to Salt Lake City, Utah, for conference with Secretary of the State Board of Health, and for study of so-called fever fever.

Surg. E. A. SWEET, proceed to Knoxville, Tenn., to examine the Whittle Springs property with regard to its suitability for use as a hospital by the Public Health Service.

P. A. Surg. LISTON PAINE, detailed as supervisor of the district comprising the Virgin Islands, for the examination and treatment of War Risk beneficiaries.

P. A. Surg. J. G. TOWNSEND, bureau orders of June 24, 1919, amended so as to fix the headquarters of the Supervisor of District No. 4 War Risk Insurance beneficiaries, at Washington, D. C., instead of Baltimore, Md.

P. A. Surg. W. C. WHITE, proceed to Chicago, Ill., to attend Red Cross conference relative to tuberculosis cases.

P. A. Surg. CARL MICHEL, detailed as supervisor of the district comprising Porto Rico, for the examination and treatment of War Risk beneficiaries.

Asst. Surg. J. D. APPLEWHITE, relieved at Petersburg, Va., in extracountry work; report for duty in rural sanitation in the State of Virginia with headquarters at Petersburg.

Prof. C. W. STILES, proceed to Montague, Tenn., from time to time to deliver addresses before the Montague Chautauque.

Surg. E. E. CARLE, Reserve, ordered to active duty in the reserve corps of the Public Health Service, effective July 1, 1919.

P. A. Surg. J. LEE ADAMS, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, effective July 1, 1919.

P. A. Surg. W. H. AXTELL, Reserve, bureau letter dated June 3, 1919, amended so as to assign him to active duty June 1, 1919.

P. A. Surg. R. W. BROWN, proceed to East Norfolk, Mass., for temporary duty.

P. A. Surg. CHARLES S. COWIE, Reserve, ordered to active duty in the reserve corps of the Public Health Service, effective July 1, 1919.

P. A. Surg. S. W. CRITTENDON, Reserve, relieved at East Norfolk, Mass. Proceed to the Marine Hospital, Boston, Mass., for duty in the examination and treatment of cases suffering from neuritis or disturbed mental conditions.

P. A. Surg. A. P. GOFF, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, effective July 1, 1919; proceed to Washington, D. C., for duty in the Division of Marine Hospitals and Relief.

P. A. Surg. GEORGE A. ROWLAND, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, effective July 1, 1919.

Asst. Surg. C. E. JAMES, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, effective July 15, 1919. Proceed to Boston, Mass., for duty at the Marine Hospital.

Asst. Surg. HENRY E. ST. ANTOINE, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, proceed to Baltimore, Md., for duty in the Marine Hospital.

Asst. Surg. DANA L. WEED, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, effective July 1, 1919.

Asst. Surg. JOSEPH E. WHEELER, Reserve, ordered to active duty in the Reserve Corps of the Public Health Service, proceed to the marine hospital, St. Louis, Mo., for duty.

Asst. Surg. ROBERT P. HARRISON, relieved at Little Rock, Ark., proceed to Greenville, S. C., for duty in the U. S. Public Health Service.

Asst. Surg. J. BALDWIN MCCOMB, relieved at Macon, Ga.; proceed to New Orleans, La., and report to supervisor of District No. 6.

Asst. Surg. I. C. MONTGOMERY, placed at disposition, Kansas, proceed to Joplin, Mo., for duty in connection with rural sanitation.

Asst. Surg. F. RUTEMAN, proceed to Washington, D. C., for duty in the Mount Airy Hospital.

Sen. Asst. C. S. BROWN, proceed to points in the States of Pennsylvania, New Jersey and Delaware, for conference relative to venereal disease control among seamen.

Sen. Asst. P. L. HELMICK, relieved at Philadelphia, Pa., proceed to Washington, D. C., for duty.

Sen. Asst. H. S. LUCAS, relieved from rural sanitation duty in the State of Virginia, proceed to Joplin, Mo., for duty in rural sanitation.

Asst. Educational Director DAVID ROBINSON, proceed to Toledo, Ohio, for conference relative to combating venereal diseases in that city.

Regional Consultant RUSSELL A. JAFFE, proceed to New York and Boston for conference with insurance officials relative to cooperation in venereal control measures.

Regional Consultant EDITH M. RABE, proceed to Auburn, Mass., to lecture before a special school of instruction for women.

Lecturer ROBERT C. BROWN, proceed to Hoppers Ferry, W. Va., Hampton, Va., and Clark Run Beach, Va., to deliver addresses on the venereal disease programme.

Resignation of Assistant Surgeon R. L. DESAI'SSIE accepted by direction of the President to be effective Oct. 20, 1919.

Medical News

(PHYSICIANS WILL CONFERENCE AND BY SEPARATE FOR THIS PERMANENT BUREAU OF STATE OF THE PUBLIC HEALTH SERVICE, INTERESTS SUCH AS RELATE TO SOCIAL ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

New Tuberculosis Clinic.—The first tuberculosis clinic was held by the Lee County Tuberculosis Association at Dixon, July 9, under the instruction of Dr. Russell E. Adams, Springfield. In the afternoon Dr. Adams conducted a similar clinic at Sterling.

Graduate Course Lecture.—The seventh lecture of the graduate summer quarter in medical sciences at the University of Illinois, Chicago, was delivered, July 23, by Prof. Leslie B. Argy of Northwestern University on "Giant Cells and Their Role in Bone Resorption."

Personal.—Dr. Samuel J. Walker, Chicago, has been awarded a medal of the third class by the Greek government. —Dr. Anna Dwyer, Chicago, fell at Ravenna Park, July 11, fracturing her arm.—Dr. John S. Sweeney, Chicago, has returned after service with the American Expeditionary Forces in France.

Public Health Campaign.—The Chicago Chapter of the American Red Cross, July 15, entered definitely on the preparatory measures for handling epidemic or other civilian disasters. It has appropriated \$15,000 for the campaign of preparedness to include courses of instruction for home nursing which will be under the charge of Mrs. John McMahon.—The new municipal nursing school for Chicago will open, August 4. The school is to be located in the old Loyola School of Medicine building on Fulton Street. The plan includes a training course of eight weeks for the women of Chicago who desire to become proficient in home nursing. Applications for admission to the school should be made to the department of health, City Hall.

INDIANA

Board Reversed.—The finding of the Indiana Board of Medical Registration and Examination in the revocation of the license of George F. Smith, Belvidere, has been reversed by the Knox Circuit Court.

Reinstatement Denied. At a recent meeting, the Indiana State Board of Medical Registration and Examination declined to restore the license of Dr. Charles L. Landfair, Bluffton, Ind., which had been revoked in 1909, for the reason that it was not satisfactorily shown by the evidence presented that he was entitled to such restoration of his right to practice.

Funds Needed for Tuberculosis Camp.—At the meeting of the Evansville Anti-Tuberculosis Society, held at Evansville, July 8, a committee was appointed to wait on the hospital campaign committee and ask for an appropriation of \$49.00 for the Bodine Camp. This money is needed for the purpose of the outing farm, and for the installation of a central heating plant.

New Reciprocal Relations.—The Indiana State Board of Medical Registration and Examination has recently established reciprocal relations with Alabama, Georgia and Washington. Relations had previously been established with Arkansas, Colorado, District of Columbia, Illinois, Iowa, Kentucky, Louisiana, Maine, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Utah, Vermont, Virginia, West Virginia, Wisconsin and Wyoming. This makes thirty-four states with which Indiana now reciprocates in the matter of medical licensure.

IOWA

Full Time Physician for City. At a joint meeting of the city council and school board of Fort Dodge, held June 5, it was decided to employ a physician who shall devote his entire time to the health work in the city including that in the city schools.

Valley Physicians Hold Meeting.—At the forty-eighth annual meeting of the Des Moines Valley Medical Association, held in Ottumwa, June 25 and 26, Dr. Loris P. Torrence,

Blakesburg, was elected president, and Drs. William S. Lessinger, Mt. Pleasant, and Lora D. James, Fairfield, vice presidents.

Personal.—Dr. Daniel C. Stellsmith, health officer of the University of Iowa and Iowa City, has been appointed city health officer of Columbus, Ga.—Dr. James S. Cooper, Burlington, has been appointed physician of Des Moines County, succeeding Dr. Benjamin F. Campbell, whose time has expired.—Dr. E. A. Kepford has resigned as state director of the Red Cross and will resume his work as state lecturer on tuberculosis.—Dr. James Dunn, school physician of Javenport, has resigned in order to permit the former school physician, Dr. Peter H. Schroeder, who has been in military service, to resume his former duties.—Dr. George B. Jenkins, professor of anatomy in the State University of Iowa, Iowa City, has resigned and is to be connected with the Carnegie Institute.

Hospital Items.—Dr. Carlisle R. Jones, Atlantic, took possession of the New Atlantic Hotel and has begun to remodel it for use as a hospital.—The Clipper Building at Clarion has been sold to Dr. Erle D. Tompkins, who will remodel and adapt the building for use as a hospital.—Vern W. Skiff, Chicago, a former citizen of Newton, has given a hospital to that city.—The preliminary plans of the new addition to the Jane Lamb Hospital, Clinton, have been approved. The plans call for a five story building to be located in front of the present building. The structure will be of brick and in harmony with the other buildings.—The controlling interests of the Marengo Mineral Springs Hospital have been purchased from Dr. Eric N. Brown and Ira N. Crow, by Dr. William P. Hutchins.—Permit for the erection of the Sunmycrest Tuberculosis Hospital, Dubuque, to cost \$150,000, has been granted.—A campaign for funds to build a \$200,000 hospital for women and children in Des Moines has been opened by the Iowa Lutherans.

MARYLAND

Hospital for Negroes Assured.—With the realization of \$51,000 collected by the colored people of Baltimore, the purchase of the Union Protestant Infirmary building for a colored hospital is assured. However, the headquarters for the fund will remain open until the \$75,000 desired is raised. Of this amount, \$25,000 will be used to buy equipment, including an up-to-date roentgen-ray machine.—The trustees of the Union Protestant Infirmary will now push their plans for a campaign to raise \$750,000 for the erection of a new hospital group on the site acquired at Homewood. Plans for the hospital will be brought to completion at once by the architect.

Personal.—Dr. W. G. Vandermin, the urologic specialist of the Island of Java, recently visited the Johns Hopkins Hospital. He will spend eight days in Baltimore engaging in further research at Johns Hopkins, when he will leave for Holland on his way back to Java. In May, 1916, he entered the medical corps of the Dutch East Indian Army, and has since then visited Holland, England, France, Spain, Japan, China and America.—Alan M. Chesney, Major, M. C. U. S. Army, Baltimore, who arrived recently in Newport News after more than two years spent in base hospitals with British and American armies in France, has been ordered to Camp Dix pending his separation from the service.—Dr. Daniel St. T. Jenifer, who served with the U. S. Medical Corps overseas, is visiting his home at Towson.—Dr. Ralph C. P. Truitt, Baltimore, has been appointed medical director of the Illinois Society for Mental Hygiene.

Reconstruction Work.—The big exhibit of reconstruction work for wounded soldiers done at U. S. Army General Hospital No. 2, Fort McHenry, in charge of Harry S. Purnell, Lieut. Col., M. C. U. S. Army (retired), opened, July 21, at the Medical and Chirurgical Faculty Building, Baltimore, and will continue for a week or ten days. It is open to the public free of charge and affords an opportunity to see the remarkable work done by surgeons at this post for the soldiers mangled and shattered by war. Besides a complete exposition of reconstruction methods, the collection includes drawings of unusual operations, sketched by artists who followed each step of the processes; reproductions of deformities before and after correction, and models, masks, casts and paintings of many descriptions. It has proved so interesting to the medical authorities at Washington that it will be moved to that city from the Medical-Chirurgical Building and made a part of the collection in the Army Medical Museum.

NEW YORK

New Regulation for Registration of Births.—In order to meet the requirements of the law passed by the last legislature, the state health department is about to issue printed forms complying with the new regulations. For all births occurring since April 14, 1919, the forms will give the name of the child, the date and place of its birth, the names of the parents, and the signature of the registrar who signed the birth certificate. The state health department urges the importance of proper birth registration on both physicians and the laity.

Personal.—Homer Folks, director of the Department of Civil Affairs of the American Red Cross, and a member of the Public Health Council of New York, has been made a Chevalier of the Legion of Honor by the French government and a Commander of the Order of the White Eagle by the Serbian government.—Dr. Henry L. K. Shaw, Albany, director of the Division of Child Hygiene in the state department of health since 1914, has resigned and will devote all his time to private practice.—Major Albert H. Garvin, Ray Brook, formerly superintendent of the New York State Hospital for Tuberculosis, who went to France in September, 1917, where he served as chief of the Bureau of Tuberculosis, Medical and Surgical Department, with the American Red Cross forces, has been decorated with the Medaille d'Honneur de Vermeil of the French government in recognition of his services to that country.

New York City

To Organize New Hospital.—Application has been made for the incorporation of the St. Bartholomew's Hospital and Clinic for the Alimentary Canal. The clinic is to be conducted at 215 East Forty-Second Street and is an extension of the work begun by the late Bishop Greer when he was rector of St. Bartholomew's Church.

Personal.—Dr. William B. Brinsmade of Brooklyn has been cited by General Pershing for exceptionally meritorious and conspicuous service in the American Expeditionary Forces. Dr. Brinsmade organized Naval Base Hospital No. 1 which took care of 3,668 battle casualties and 504 cases of pneumonia.—Dr. John Leonard Kantor has been released from army service.

Physicians Face Prosecution.—Summonses for more than 8,000 physicians, dentists, druggists and veterinarians authorized to dispense narcotic drugs, who failed to register with the state department of narcotic drug control on or before July 1, as required by law, are being issued. Violation of this law is a misdemeanor punishable by revocation of license and other penalties.

Sold Fake Diplomas.—According to a news report, Nicholas D. Clements, New York, pleaded guilty, July 7, to selling a bogus medical diploma to Abraham Lazinsky of Brooklyn for \$1,500. Clements asked leniency on his promise to reveal the names of seventy-five men now practicing as physicians and attorneys on "credentials" sold by him. Clements is serving a term at Dannemora prison.

The Jacobi Will.—The will of the late Dr. Abraham Jacobi disposes of an estate of approximately \$300,000. His daughter, Mrs. Margaret McNaney, is the residuary legatee. Bequests of \$5,000 are made to the New York Academy of Medicine, and to a niece and a nephew. The Academy of Medicine is also to take such of the decedent's medical books, journals and surgical instruments as may be selected. Dr. Abraham L. Goodman is to have such books and surgical instruments as he may select. Other friends are to receive medical books and surgical instruments. The United States Civil Service Reform Corporation is to receive \$1,000. A few other minor bequests are provided.

NORTH CAROLINA

Personal.—Dr. Claude P. Fryer, Greenville, has resigned as county health officer of Pitt County.—Coile L. Sherrill, Major, M. C. U. S. Army, Satesville, has been promoted to the rank of lieutenant-colonel, Medical Corps.

Medical Building for Charlotte. At a meeting of physicians, lawyers, real estate men and investors in Charlotte, June 26, the feasibility of a medical building was discussed, and a committee was appointed to perfect plans for organizing a corporation to put up the building, to select a suitable site and to make general plans for carrying out the purpose of the meeting.

State Board Items.—Drs. Richard H. Lewis, Raleigh, and J. E. Tucker (D.D.S.), have been appointed members of the state board of health for a term of six years.—At the annual meeting of the North Carolina State Board of Medical Examiners, held at Raleigh, June 24 to 27, Dr. John Quiney Myers, Charlotte, was elected president, and Dr. Hubert A. Royster, Raleigh, was continued as secretary-treasurer of the board.

Hospital Notes.—The Grand Lodge of Free Masons of North Carolina has authorized the erection on the grounds of the Masonic Orphanage at Oxford, of the William J. Hicks Memorial Hospital to cost about \$75,000. It will be a structure of reinforced concrete, three stories in height and with accommodation for fifty patients.—The Montgomery Home in Concord is being remodeled so that it may be occupied by the Concord Hospital. After the changes are made there will be provision for twenty-five rooms and an open ward to contain ten patients.—The Richard Baker Hospital has been reopened at Hickory.—The Infants' and Children's Sanatorium at Saluda opened for the year, May 25. This institution is devoted exclusively to the treatment of babies and children.—President R. B. Babington of the North Carolina Orthopedic Hospital has received instructions from the building commission to go ahead with his plans for the erection of a hospital for the treatment of crippled children. The institution has at present a site of 28 acres, and \$70,000 for the building fund. The hospital is to be located at Gastonia.

OHIO

Memorial to Physician.—A memorial tablet in memory of Dr. Julius H. Jacobson, Toledo, was dedicated, July 10, in the auditorium of the nurses' home of St. Vincent's Hospital.

Anesthetists' Organization.—The Toledo Association of Anesthetists was organized, July 1, and the following officers were elected: president, Dr. Elmer J. McKesson; vice president, Walter Hartung; secretary and treasurer, Dr. Paul P. Gintzel.

Northern Ohio Physicians' Outing.—At the outing arranged for the physicians of northern Ohio at Cedar Point, July 17, by the Ohio State Medical Association, the principal address was delivered by Dr. Harold N. Cole, Cleveland, director of the Bureau of Venereal Diseases for the state of Ohio, on "Venereal Diseases, Their Diagnosis and Control."

Honor Retiring Executive Secretary.—The council of the Ohio State Medical Association gave a dinner, July 6, at Columbus in honor of Mr. George V. Sheridan, executive secretary of the association, who has become publisher of the Springfield (Ohio) Star. On behalf of the association, Dr. John H. J. Upham, Columbus, presented a completely equipped automobile hamper to Mr. Sheridan.

Personal.—Dr. Edison B. Starr, Springfield, has been appointed director of industrial hygiene and medicine by the state board of health, with headquarters at Columbus.—Dr. Klor L. Parent has been appointed head of the Federal Clinic, Lima, succeeding Dr. Aldo V. Silbert, who has resigned.—Dr. J. Carroll McGinnis, Martins Ferry, is reported to be seriously ill.—Dr. James H. Bennett, Youngstown, who was appointed president of the board of education, had a cerebral hemorrhage, June 29.—Dr. Ora O. Fordyce, Athens, has succeeded Dr. George R. Love, Toledo, resigned, as superintendent of the Toledo State Hospital.

PENNSYLVANIA

Hospital Dedicated.—The Sacred Heart Hospital, Allentown, which has been erected at a cost of nearly \$200,000, will be dedicated, August 31, in connection with the golden jubilee celebration of the Sacred Heart congregation.

Second Summer School Held.—The second summer camp of the state department of health opened at Abbot, Alto, July 6, for an instructional course of two weeks under the charge of Dr. Edward Martin, Philadelphia, state commissioner of health, and Dr. John D. McLean, assistant commissioner.

Personal.—Dr. Walter A. Dearth, Pittsburgh, has been elected a member of the Allegheny County prison board.—Dr. James F. Edwards, Pittsburgh, for many years director of the department of health at Pittsburgh, has been appointed health commissioner of Omaha.—Dr. Joseph D. Findley, Altoona, has been elected chief of the staff of the Altoona Hospital, to fill the vacancy caused by the resignation of Dr. Orr H. Shaffer, who, on account of ill health, will spend a year in California.

PHILADELPHIA

Personal.—Cheney M. Stimson, Major, U. S. Army, who served with Base Hospital No. 82 at Toul, France, has returned from overseas.—Dr. Jacob Solis-Cohen at the annual meeting of the Philadelphia Laryngological Society, June 3, was elected honorary president for the term of his life.

Government Returns Hospital.—An agreement has been reached between the War Department and the department of health and charities relative to the lease of a section of the buildings of the Philadelphia General Hospital, which were used by the government during the latter part of the war with Germany as a reconstruction hospital for wounded soldiers and sailors. After the lease of the buildings, which was effected by Director Krusen of the department of health and charities and Secretary of War Baker, the government fitted up the structure with considerable hospital equipment, all of which now becomes the property of the municipality. The buildings were leased at an annual rental of \$1.

Preventive Medicine Course at Woman's Medical College.—Dean Tracy, of the Woman's Medical College, has outlined courses calculated to meet the specific needs of medical women in the great field of public health education. These courses have been approved by the interdepartmental social hygiene board, from which a grant of money has been received by the college which enables it to undertake the development of the work this year, pending the fall campaign which shall enable the college to establish a department of preventive medicine. Courses adapted to the needs of the medical women, who are preparing for social work in which a medical background is necessary, are included in the curriculum of the new department. All students entering must undergo physical examination.

RHODE ISLAND

Personal.—Dr. Fenwick Gordon Taggart, East Greenwich, a veteran of the Spanish-American War and who has been overseas for more than a year, has been commissioned major, M. C., U. S. Army.—Dr. John H. Doyle, Providence, now on duty with the Army of Occupation in Germany, has been promoted to the rank of major, M. C., U. S. Army.

Society Meets at State Infirmary.—At the annual meeting of the Kent County Medical Society, held at the State Infirmary, Howard, June 19, a child welfare clinic, a clinic on mental diseases, a surgical clinic and a medical clinic were held, and at the conclusion, lunch was served and the society was entertained by Dr. Henry A. Jones, superintendent of the institution.

Medicolegal Society Election.—The annual meeting of the Rhode Island Medico-Legal Society was held, June 26, at Slocumb's-on-Pawtucket, under the presidency of Dr. Byron C. Richards, Pawtucket, and the following officers were elected: president, Dr. Henry A. Jones, Howard; vice president, Henry D. J. C. Dubois, and secretary-treasurer, Dr. Harry S. Flynn, Providence.

Tuberculosis Prevention.—The Rhode Island Anti-Tuberculosis Association in its eleventh annual report states that in the state there are at present twenty-four local tuberculosis associations, seven sanatoriums and hospitals and preventoriums, seven open air schools, and ten dispensaries. A tuberculosis bureau has also been established by Dr. Charles V. Chapin in the health department.

SOUTH CAROLINA

United States Public Health Service Work at Columbia Ends.—The United States Public Health Service which has maintained an office in Columbia since September, 1917, turned over its work to the state and city health organizations, June 30. During this period the public health service has disbursed more than \$75,000 in the protection of the health of military forces and civic health population of Columbia.

Personal.—Dr. Richard L. DeSaussure, Charleston, has been elected commissioner of health of Floyd County, Ga., succeeding Dr. Mather M. McGold.—Dr. James A. Hayne, Columbia, state health officer, who has been very ill in a hospital in Washington, is reported to be improving at his home in Greenville.—Dr. Edward C. L. Adams, Columbia, has been appointed game warden.—Dr. C. Frederick Williams, Columbia, who has been seriously ill, is reported to be convalescent.—Dr. Chamney M. Rakostraw, Rock Hill, has been made surgeon of the Pryor Hospital, Chester.

Graduation Exercises.—At the annual commencement exercises of the Medical College of the State of South Carolina, Charleston, held June 5, fourteen degrees in medicine and three in pharmacy were conferred. The annual commencement address was delivered by President W. S. Currell of the University of South Carolina. It is announced that Dr. Lane Mullally, Charleston, professor of obstetrics and vice dean of the faculty for thirty years, has resigned. Dr. Francis L. Parker, Charleston, has been elected vice dean of the institution; Dr. G. Fraser Wilson, professor of obstetrics; Drs. Julius C. Sosnowski, Edward H. Sparkman, Jr., and Joseph S. Kham, assistant professors of surgery; Dr. J. M. Jordan, professor of botany and pharmacognosy; Dr. Henry W. DeSaussure, lecturer on gynecology; Dr. William H. Frampton, assistant in obstetrics and medicine; and Dr. Olin B. Chamberlain, assistant in medicine.

Hospital Notes.—At the annual meeting of the stockholders of the Gaffney City Hospital, June 27, J. A. Carroll was reelected president, and Drs. James N. Nesbitt, Stuart B. Sherard and Robert T. Ferguson, all of Gaffney, directors. —The work on the Spartanburg General Hospital will probably be commenced this month. The new institution will be a merger of the Good Samaritan Hospital and the Spartanburg Hospital and will be known as the Spartanburg General Hospital. The structure will be of reinforced concrete and fireproof. The site contains 7½ acres and was purchased at a cost of \$20,000. —The Abbeville County Memorial Hospital has been granted a commission with a capital of \$100,000. The petitioners state that it is their purpose to establish in Abbeville a hospital in memory of soldiers from Abbeville County who died in the recent war. —The pathologic laboratory of the Columbia Hospital, built and equipped with funds given by Mrs. T. G. Croft, in memory of her husband, the late Dr. T. G. Croft, Aiken, was dedicated recently.

TENNESSEE

State Board Moves.—Quarters for the state board of health have been secured in the capitol annex on Seventh Avenue, Nashville.

Hospital Cornerstone Laid.—The cornerstone of the Tri-State Methodist Episcopal Hospital, Memphis, was laid, June 12. It is estimated that the building will cost \$1,000,000.

New Medical Building.—The board of trustees of the University of Tennessee is planning to erect a building for the medical department of the university at Memphis, to cost \$100,000.

Personal.—Dr. William O. Sullivan, Newbern, was painfully injured by the overturning of his car between Newbern and Yorkville, July 2. —Dr. I. C. Ramsey, a colored physician of Gallatin, was assaulted while making a professional call, June 3, and is under treatment in a hospital in Nashville.

New Officers.—The West Tennessee Medical and Surgical Association held its annual meeting in Deersburg, May 30, and the following officers were elected: president, Dr. John D. Brewer, Newbern; vice president, Dr. Harley W. Qualls, Union City; secretary, Dr. Isaac A. McSwain, Paris (reelected).

Physician Loses Suit.—A suit directed by Dr. Ben Friedman of Memphis, against the Tennessee State Board of Medical Examiners, based on the allegation that his license was maliciously revoked, was recently dismissed by the court. Reports indicate that the board revoked his license about a year ago on charges that Friedman had violated the Harrison Narcotic Law.

CANADA

New Brunswick Medical Society.—At the final session of the annual meeting of the New Brunswick Medical Society, held in St. John, July 15 and 16, a special committee brought in a report, which the society subsequently adopted, affirming that alcohol is a medicine and a necessary drug, and should be under no more restrictions than any other drug. It was also declared that special pre-emption blanks in connection with alcoholic prescriptions are inconvenient and unnecessary.

Personal. Lieut. Col. John Anyot, Toronto, professor of hygiene and preventive medicine in the University of Toronto, who has been overseas for three or four years as sanitary officer to one of the Canadian divisions, has been appointed deputy minister of the newly created federal department of public health at Ottawa. —Dr. Wilfrid T. Grenfell, C. M. G., the Labrador medical missionary, has been in Ottawa in the

interest of several hospitals he is establishing in that section of Canada. —Major David A. Clark, Toronto, who has had more than four years' service overseas, has been appointed to the staff of the Military Neurological Hospital at Vancouver. —Major Herbert G. Murray, Owen Sound, Ont., who enlisted with the Queen's University Hospital, Kingston, has returned to Owen Sound and reentered private practice.

GENERAL

Coming Meeting.—The thirty-second annual meeting of the American Association of Obstetricians and Gynecologists will be held in Cincinnati, September 15 to 17, under the presidency of Dr. John F. Erdman, New York; Dr. Magnus A. Tate is chairman of the local committee of arrangements.

District Society Election.—At the annual meeting of the Iowa and Illinois Central District Medical Association, held at Davenport, July 10, the following officers were elected: president, Dr. William D. Chapman, Silvis; vice president, Dr. Gordon F. Harkness, Davenport; secretary, Dr. Arthur E. Williams, Rock Island (reelected); and treasurer, Dr. Thomas D. Starluck, Davenport.

Secretary of Council on Pharmacy and Chemistry Honored.—In connection with the ninety-eighth annual commencement exercises of the Philadelphia College of Pharmacy, the degree of Master of Pharmacy was conferred on Prof. William A. Puckner, Chicago, secretary of the Council on Pharmacy and Chemistry of the American Medical Association. The degree was conferred by the Dean, Dr. Charles H. LaWall.

Chattahoochee Valley Physicians Elect Officers.—At the nineteenth annual meeting of the Chattahoochee Valley Medical Association, held in Columbus, Ga., July 9 to 11, Warm Springs was selected as the next place of meeting and the following officers were elected: president, Dr. Hugh McCulloch, West Point, Ga.; vice president, Dr. Walter A. Weed, Birmingham, Ala.; and secretary-treasurer, Dr. William J. Love, Opelika, Ala. (reelected).

New Officers.—The Association of American Physicians, at its annual meeting in Atlantic City, June 16 and 17, elected the following officers: president, Dr. Hermann M. Biggs, New York; vice president, Dr. William S. Thayer, Baltimore; secretary, Dr. Thomas McCrae, Philadelphia; recorder, Dr. Thomas K. Boggs, Baltimore; treasurer, Dr. Joseph A. Capps, Chicago, and counselor, Dr. Lewis A. Cramer, New York. —The annual meeting of the American Society for Tropical Medicine was held in Atlantic City, N. J., June 16 and 17, and the following officers were elected: president, Henry L. Nichols, Colonel, M. C. U. S. Army, Washington, D. C.; vice presidents, Drs. John M. Swan, Rochester, N. Y., and Carl F. Meyer, San Francisco; secretary and treasurer, Dr. Sidney K. Simon, New Orleans, and assistant secretary, Dr. Allen J. Smith, Philadelphia. New Orleans was selected as the next place of meeting.

Legislation for Influenza Control.—The first step in the way of obtaining legislation to combat a recurrence of the influenza epidemic has been taken in Congress by the introduction of a measure by Congressman Eugene Black of Texas. The bill provides an appropriation of \$500,000 for the investigation of the causes, modes of transmission, prevention and cure of influenza, pneumonia and allied diseases, and the fund is also made available for combating these diseases. This sum is made available until July 1, 1922. The Public Health Service is charged with the expenditure and administration of this work. The Surgeon-General of the Public Health Service is authorized to employ such medical assistance and nurses as may be necessary, fixing their compensation at not greater than the amounts paid other similar employees of the Public Health Service. The Surgeon-General is directed to file an itemized list of expenditures with Congress, December 1 of each year. A preamble to the measure declares that the influenza epidemic caused 500,000 deaths in the United States, that influenza and pneumonia cause one tenth of all the deaths in the United States, that medical science is not yet in possession of complete data regarding these diseases, and that they are of grave social concern to the United States. The bill is No. 7293, and was referred to the House Committee on Appropriations, of which Congressman James W. Good of Iowa is chairman, for action.

A Bill for a National Department of Health.—Hon. Joseph I. France, U. S. Senator from Maryland and chairman of the Senate Committee on Public Health and National Quarantine, introduced on July 17, Senate Bill 2507 creating a department of public health. The bill follows the general plan of the Owen Bill, with some important modifications.

It provides for a department of public health under the direction of a secretary, who shall be a member of the cabinet, and for three assistant secretaries, the first assistant to be a man trained in medical science, public health and sanitation; the second to be an expert in vital statistics; and the third to be a woman trained in medicine or nursing and public health. The U. S. Public Health Service and the Bureau of Chemistry are to be transferred to the new department, which is also to have bureaus on vital statistics, sanitation, hospitals, child and school hygiene, quarantine, food and drugs, nursing, tuberculosis and personnel. The secretary of public health is directed to communicate with the governor of each state requesting him to recommend to the legislature suitable legislation with adequate appropriations to secure cooperation between the federal department of public health and the state board of health. Every state taking such action is to be entitled to its proportionate share of such funds as may be appropriated by Congress for carrying out the provisions of the act. The secretary of public health is also directed to divide the United States into health states, districts, subdivisions and precincts, each conforming to the geographical boundaries of the various political divisions. Each state is to create a state board of health with a state health officer and a health officer for each district, subdivision and precinct, the secretary of public health to appoint these state officers as federal health officers "so that in each cooperating state every health officer of said state or of each district, county or precinct therein is by virtue of his selection by the local authorities become also a federalized officer and as such an integral part of the Department of Public Health." The Department of Public Health is directed to cooperate with the Departments of Commerce, Labor and the Interior in the collection of vital statistics and to establish a uniform system of cards, records and reports regarding diseases, disabilities, industrial accidents, births, deaths, physical condition of schoolchildren, the number and condition of existing hospitals, etc. The bill provides for the appropriation of \$15,000,000 for 1920 to be prorated among the states in proportion to their population as soon as the states comply with the provisions of the law and the regulations of the secretary of public health, provided that each cooperating state must contribute to the public health work a sum equal to that contributed by the federal government and that it must make full and complete reports of births, deaths and morbidity. It also appropriates \$48,000,000 for the construction of sanatoriums and hospitals, this sum to be distributed among the states in proportion to their population, each state receiving its allotment to provide an equal amount, also location, plans and means of future support for the proposed hospital.

FOREIGN

Conference of Manufacturing Chemists in Italy.—The First National Congress of the Manufacturing Chemists of Italy is to convene at Barcelona in October with an exhibition annex.

Smallpox at Barcelona.—There has been a rather serious outbreak of smallpox in Barcelona. The papers there attribute it to the migration of patients from other parts of Spain.

Special Belgian Ear and Throat Meeting.—The Société belge oto-rhino-laryngologie met at Antwerp early in July and invited French and other specialists to attend, an official reception being tendered the visiting confrères by the municipal authorities.

Army to Fight Typhus.—An expedition to combat typhus in Poland is being organized in Paris under the command of Harry L. Gilchrist, Col., M. C., U. S. Army. The expedition will consist of 550 officers of the Medical Corps, and volunteer sanitary experts.

Reappearance of Belgian "Scalpel." The dean of medical journals in Belgium, *Le Scalpel*, has taken the initiative to merge in one single and important journal the various small medical journals published in Belgium before the war, none of which have been revived to date.

The Pozzi Sale.—The last week in June the collections of the late Professor Pozzi were auctioned off at the Petit galleries at Paris. The collection included thirty choice paintings of different schools, tapestries, bronzes, antique rugs and furniture, miniatures, etc., all said to have been selected with exquisite taste.

Tuberculosis Funds at Madrid.—The *Fiesta de la Flor* (Flower Day), held annually at Madrid for the purpose of collecting funds to care for tuberculous patients, produced this year the sum of 160,000 pesetas (about \$32,000), which is the largest amount collected since this custom was inaugu-

rated six years ago. It is estimated that tuberculosis causes 50,000 deaths every year in Spain.

Swiss Ophthalmologic Congress.—The twelfth annual meeting of the *Gesellschaft der schweizerischen Augenärzte* was held at Basel in July. The principal subjects discussed were detachment of retina and injections of milk in treatment of various eye affections. Vogt of Basel reported the experimental production of cataract by isolated short-waved ultra red plus red rays. Also experimental depigmentation of the living iris by the same. Also a demonstration of the visibility of the endothelium of the living cornea by means of the cornea microscope and Gullstrand's lamp.

Losses in the Profession in Italy During the War.—The *Riforma Medica* cites recently published statistics to the effect that 1,040 members of the medical and nursing professions in Italy died from wounds or illness contracted at the front. This includes 317 army physicians, 10 in the navy, 42 of the Red Cross service and others in the merchant marine, to a total of 377 registered physicians. There were also 216 medical students killed and 40 pharmacy students, 23 veterinarians and 22 veterinary students. Orderlies, nurses and others bring the total to 1,000, and 300 of this number had been decorated for special gallantry or devotion or both. Of the 377 physicians, 30 died in prisons in Austria, Hungary or Germany or at the front in Macedonia, Albania or Libya.

Child Welfare Methods in France.—The officials of the Department of the Seine Inférieure, with a population of about 2,000,000, have taken over and provided for the permanent maintenance of an organization for the protection of mothers and children which was installed by the American Red Cross in 1918. The organization includes a model clinic for children, prenatal clinic for prospective mothers, a dental clinic, a school for social service workers, courses for midwives, school teachers and students, a maternity hospital with a capacity of 1,600, a school for children accompanying prospective mothers, a children's hospital with 100 beds, and a model dairy farm. This work has been in charge of Dr. Walter K. Ramsey, St. Paul, assistant professor of pediatrics in the University of Minnesota Medical School.

Typhus Train Aids Russian Refugees.—A specially equipped typhus train, financed by funds supplied by the International Sanitary Commission and managed by the Red Cross, has traveled from Vladivostok to the Ural Mountains, its staff of physicians and nurses ministering to persons afflicted with the malady and instructing the people in preventive measures. At the present time this train is operating among the soldiers of the Kolchak government on the Perm front. Many carloads of drugs and medical supplies have been provided for the men of the Russian army. A special Red Cross mission, which recently made a survey of the situation in western Siberia, found that many of the hospitals had been stripped of drugs, instruments and surgical dressings. The Red Cross is equipping these institutions. In all, about 40 tons of drugs have been shipped from America since last September. About 1,500 refugees remain in and around Vladivostok, and these have been concentrated in barracks a few miles outside of the city. Labor is in demand around Vladivostok, and this fact has greatly reduced the number of refugees.

Medical Assistance to Siberia. Drugs, clothing, foodstuffs and miscellaneous supplies valued at more than \$5,000,000 have been distributed over Siberia by the American Red Cross during the last nine months. At present nine hospitals are being operated by the organization in Siberia with a total capacity of 4,000. The relief work of Siberia has been in charge of Dr. R. B. Tensler, who has for several years been in charge of the St. Luke's Hospital, Tokyo, Japan. The headquarters of the commission are at Vladivostok where two hospitals are being maintained. New hospitals were established recently at Irkutsk and Chelyabinsk. The other Red Cross hospitals are at Omsk, Tumen, Tomsk and Novonikolaevsk. A hospital for typhus fever is also in operation at Petropavlovsk. The spread of typhus in this territory has been checked to a great extent by the establishment of bathing and disinfecting stations along the line of the railway. At one of these stations at Ekaterinburg, in one month, baths were provided for 35,000 persons, the clothing of these persons was disinfected, and new garments supplied wherever necessary.

Deaths in the Profession Abroad.—Dr. M. de Tolosa Latour, Madrid, one of the most prominent physicians of Spain, died in the early part of June. Dr. Tolosa Latour was a member of the Royal Academy of Letters and had been a leader in public health matters, especially in all relating to child

hygiene and tuberculosis prevention. He was also instrumental in founding the first seashore sanatorium for children in Spain. He had been for many years a frequent contributor to medical journals and an author of note. He was founder of the *Sanatorio Marítimo* at Chipiona, secretary for fifteen years of the *Consejo Superior de Protección a la Infancia*, and leader in welfare work for young children in general.—The death is reported of Dr. Luigi Luciani, professor of physiology and rector of the University of Rome, senator since 1905, long member of the *Consiglio Superiore della Istruzione* and of numerous scientific societies at home and abroad, aged 79. The Neurologic Society of London elected him to fill the place left vacant by the death of Brown-Sequard. His name is connected particularly with the periodical activity of the heart, the motor and sensory centers in the brain, the cortical pathogenesis of epilepsy, the static action of the cerebellum, and the physiology of fasting. In his research and in his teaching he was guided by the conception of the unity of medical science in general and the inseparability of physiology and pathology, always urging his pupils to "think physiologically."—Dr. Gabriel Corin, professor of legal medicine at the University of Liège after serving as assistant professor of physiology, founder of the *Archives Internationales de Médecine Légale*, and frequent contributor to scientific journals, especially those devoted to physiology, anthropology and criminology.

LATIN AMERICA

Sanitary Regulations in Haiti.—The new sanitary regulations adopted in Haiti have been recently published in the *Official Journal* of that country.

Hookworm Disease in Salvador.—The first permanent station to combat hookworm disease in the republic of El Salvador has been opened by the Rockefeller Foundation in the city of Santa Ana.

Sanitary Campaign in Costa Rica.—The last message of the president of Costa Rica states that the government intends to carry out during the present year an active sanitary campaign all over the republic.

Permanent Pharmaceutical Exhibition in Paraguay.—The National Society of Pharmacy of Paraguay has decided to commence a permanent exhibition of pharmaceutical, biological and chemical products, laboratory apparatus and in general of everything relating to pharmacology.

Physicians in Chile.—According to the report on public education in Chile for 1917 just published, there were granted during that year by the University of Chile, 327 degrees of doctors in medicine, 201 degrees of masters of medicine, and 351 degrees of bachelors of medicine, out of a total of 9,217 degrees conferred by the university.

Yellow Fever in Ecuador.—The director of sanitation of the Guayas department has presented a report to the government on the work so far conducted by the Rockefeller Foundation against yellow fever in that country. The results are already apparent in the gradual decrease of yellow fever at Guayaquil as shown by the number of cases which were eighty-eight in December and only seventeen in March.

Medical Students in Paraguay.—During the year 1918 there were in the School of Medicine of Paraguay two professors and forty-three first year students and in the School of Obstetrics two professors and twenty-four students. The School of Pharmacy had seven professors and sixteen students. The government has provided the necessary funds for the opening of a laboratory and institute of physiology.

Quarantine Regulations in Santo Domingo.—The new quarantine regulations prescribed by the director of public health of Santo Domingo were put in force, July 1. According to these regulations, the quarantinable diseases are cholera, smallpox, yellow fever, typhus fever, bubonic plague and leprosy. New regulations for the eradication of mosquitoes have also been adopted and published in the *Official Journal*.

Uniformity in Vital Statistics.—One of the regulations adopted at the First American Congress of Commercial and Economical Expansion held recently at Montevideo, recommends that the different American governments organize systematically their services of vital statistics so that they can soon begin the annual preparation of mortality tables. It is also recommended that the capital of some American country be designated for the location of an international office of demography, Santiago de Chile being suggested for that purpose.

PARIS LETTER

PARIS, July 3, 1919.

Special Privileges for the War Wounded

A recent order of the Paris prefect of police establishes the use of special car tickets to be furnished to war-blinded or mutilated men whose condition makes long standing in line difficult. These special tickets will permit them to go out on the platforms of the "Metropolitan" instead of waiting in the line.

Death of Professor Carrieu

The death of Dr. Carrieu, aged 60, who held the chair of clinical medicine at the Montpellier School of Medicine, has been reported.

A Special War Fund

The special war fund committee of the Association générale des médecins held a meeting recently at the Paris School of Medicine, under the presidency of Dr. Louis Mourier, under-secretary of state for the medical department of the army. Drs. Bourgeois, Bellencontre and Bongrand spoke somewhat at length of the activities of the war fund committee, pointing out the various forms of aid that had been rendered by the society. The sum of \$180,000 has been disbursed, which has insured mainly to the benefit of the physicians of the invaded territory, the widows and orphans of physicians, and students bereft of the necessary resources to continue their studies.

Competitive Examinations for Hospital Internships

The question of the resumption of the French custom of holding competitive examinations to decide what candidates shall be admitted as hospital interns possesses, at this time, a lively interest in certain circles. In September, 1918, the so-called provisional interns presented to the examining board a petition to the effect that they might be granted the privilege of entering on their full rights as interns without further examination. In answer to this petition the examining board has reached the following decision:

The provisional interns who were appointed as a result of the competitive examination held in 1913; who, at the present time, are actually serving as such; who have belonged at least a year either to a fighting unit or to a field unit; or who, if they remained in the army for less than a year, were granted a furlough or a permanent discharge for reasons of disability; or who have been given a compensation allowance on account of wounds or sickness; or who have, for similar reasons, been transferred to the reserve, are hereby appointed hospital interns without further examination. The so-called externs who were declared admissible to the competitive examination for internships held in 1913, provided they have taken part in all the tests of this examination and have fulfilled otherwise, from a military standpoint, the conditions enumerated above, are hereby appointed provisional hospital interns without further examination. The first competitive examination for hospital internships to be held in the future will be reserved exclusively for: (1) hospital "externs" who have fulfilled the conditions enumerated above, and (2) provisional interns who were not mobilized or who were not mobilized under the conditions indicated above; including also women who have been admitted as provisional interns.

LONDON LETTER

LONDON, July 2, 1919.

Defeat of the Dogs' Protection Bill

The opposition of the profession to the dogs' protection bill (THE JOURNAL, June 14, p. 1782) has been successful. The third reading has been defeated by a majority of 101 to 62. Sir Watson Cheyne led the opposition. He said the bill ought not to be proceeded with, because it implied very grave censure, for which there was no justification, on a large body of honorable men and on a great profession. He did not think the house recognized what an amount of obloquy and abuse had been poured on men who were trying to obtain knowledge which might be of great value to mankind. The original act relating to vivisection was founded on the prevention of unnecessary pain being inflicted on animals; the house had gone fully and carefully into the matter; and to pass this bill now would imply that cruelty was being inflicted and that the medical profession delighted in torture. When he began bacteriologic research, which was then in its infancy, he had difficulty in obtaining admission to a licensed laboratory and in securing two signatures on his license, because at that time practicing surgeons and physicians did not think very much of bacteria, and in some cases were entirely opposed to Lord Lister's revolutionary

surgery. Now it was proposed to add another restriction in the form of a certificate to show that no animal other than a dog could be used for the purpose of a desired experiment. There was a great deal of exaggeration about experiments on animals. It was monstrous to say they were going to get results by watching patients or by postmortem examination. In the case of poison gas were they to sit still and watch the patient till he died? Because that was what it came to if they were not to be allowed to use dogs. The whole history of medicine was full of instances of prolonged observation of patients and postmortem examinations without arriving at any result, and something achieved almost at once by experiment.

Presentation to Sir William Osler

Some of the pupils, colleagues and friends will present to Sir William Osler a collection of essays on the day before his seventieth birthday, which falls on July 12. The presentation will be made by Sir Clifford Allbutt at the Royal Society of Medicine. The contributions to the volume were collected by a committee of which Dr. William H. Welch was chairman and Dr. Casey A. Wood was secretary. The committee was composed of the following American members: Drs. Harvey Cushing, Charles L. Dana, Field H. Garrison, Abraham Jacobi, G. E. de Schweinitz, Henry Barton Jacobs, Francis J. Shepherd and Horatio C. Wood. The British members were Col. J. G. Adams, F.R.S., Dr. Raymond Crawford, Sir Bertrand Dawson, Sir William Fletcher, Prof. Arthur Keith, Sir Andrew Macphail (McGill University, Montreal), Sir D'Arcy Power, Sir Humphry Rolleston, and Dr. Charles Singer of Exeter College, Oxford, who has acted as secretary of the English section. An engraved portrait of Sir William Osler forms a frontispiece reproducing as nearly as possible the printers' and binders' arts of the fifteenth century. The essays formed two large octavo volumes each, of over 700 pages. The number of contributors both English and American is about 100. The contributions cover the history of medicine, medical education and research, pathology and therapeutics, thus reflecting the interest of Sir William Osler. There will be only one printing of the book, and the supply is limited to subscribers. The subscription is \$10.

Deaths from Arsphenamin (Neo-Arsphenamin)

Distressing fatalities from the use of arsphenamin (neovarsphenamin) continue to occur, though they are frequently not recorded in the medical press. Within ten days three deaths have occurred at the Royal Infirmary, Hull, in which the patients manifested epileptiform convulsions after the injections. At St. George's Hospital, London, a girl aged 16 was treated with injections of the novarsenobillon brand of neo-arsphenamin. An injection which was to have been the last proved fatal. A crop of these cases occurred during the war and were put down to some chemical impurity in the drug, which came from the same firm. In the present case the medical evidence was to the effect that death was due to pneumonia consequent on injection of the novarsenobillon.

MEXICO LETTER

MEXICO, July 13, 1919.

Reappearance of Yellow Fever

Yellow fever, which for many years used to ravage our ports regularly, but which has not been present for a long time, has appeared again in the state of Yucatan, causing the death of two persons. The disease has assumed epidemic form and has spread to the states of Campeche and Chiapas. The sanitary authorities have taken the necessary precautionary measures and have reported the presence of the disease to the sanitary authorities of other countries, as required by international conventions. It is expected that a commission of bacteriologists will be appointed to carry out confirmatory studies in regard to the etiologic role which *Leptospira icteroides* plays in the disease according to the investigations of Noguchi. These studies were first known here through the article published in THE JOURNAL. The reappearance of yellow fever furnishes an excellent opportunity to make further investigations with respect to inoculation and immunotherapy in connection with the disease, since it appears that the etiologic germ is already known.

The Organization of the Mexican Medical Association

The organizing committee for the proposed Mexican Medical Association has been appointed. It will be the endeavor of the committee to secure the indorsement of the plan on the part of the physicians, and it will also prepare by-laws

for the association. Dr. Eduardo Licéaga has been elected honorary president, Dr. Gregorio Mendizábal, president, and Dr. Jesus Monjaras, secretary, in addition to other physicians who will act as vice presidents, treasurer and members of the committee. The secretary's address is calle Ezequiel Montes, No. 11, Mexico City.

The Prohibition Movement

The governor of Sonora has ordered that any one found manufacturing alcoholic drinks or dealing in them shall be shot.

Repeal of Tax on Physicians

The tax on the exercise of the liberal professions, which included that of medicine, has recently been repealed.

Regulation of the Practice of Medicine

The state of Puebla has promulgated a law governing the practice of medicine in accordance with which this profession can be practiced in that state only by those persons possessing legally acquired degrees and who can prove their identity. In towns in which there are no licensed physicians, laymen may be permitted to practice after filing the proper application and obtaining a permit, which will be granted only after an examination has been passed with a view to ascertaining the character of the applicants, education and their knowledge of the healing art. So far only the states of Jalisco and Puebla have legislated on this subject. In the other states complete freedom, with the abuse of privilege, prevails, the existing condition being called here, probably for euphemistic reasons "libertad de profesiones" (professional liberty).

Personal

Dr. Macias, the president of the University of Mexico, has returned from the United States where the honorary degree of LL.D. was bestowed on him by the University of Arizona. He visited several colleges in Arizona and also in Texas and California.—Dr. S. Burt Wolbach, of Harvard, who came to this country to make certain studies on typhus fever, has returned to the United States. No report of the result of his investigations was made by him here.—Dr. Aristeo Calderón, a member of the National Academy of Medicine for many years, a legal expert of the courts of justice and lately chief of the medicolegal corps of the army, died, July 4, of pneumonia.—Dr. Alberto Oviedo, who until recently was president of the University of Mexico, has left for the United States, where he intends to make certain special studies on behalf of the government.

Marriages

CARLTON IRA WOOD, Lieut.-Com., M. C., U. S. Navy, on duty at the U. S. Naval Hospital, New London, Conn., to Miss Margaret A. Miller of Wadsworth, Ohio, June 24.

HERMAN ALFRED HEISE, Lieut., M. C., U. S. Army, North Lake, Wis., on duty at Fort Oglethorpe, Ga., to Miss Eugenia May Rothrock, at Fort Oglethorpe, recently.

AYDELOTTE WILL WHEATON, Chincoteague, Va., to Miss Louise Florence Dowling-Peters of London, England, at Atlantic City, N. J., June 27.

WILLIAM WELLES HOYT, Capt., M. C., U. S. Army, Chicago, to Isabel Doan Brownlee of the American Red Cross, in Paris, France, May 27.

REGINALD MYERS ATWATER, Boston, to Miss Charlotte Martin Penfield of Englewood, N. J., at Silver Bay, N. Y., July 10.

ROBERT CROW HAMILTON, Indiana Harbor, Ind., to Miss Roma Jane Earnest of Seymour, Iowa, June 26.

HARRY BRADFORD NORTON to Miss Zella Elzea, both of Center, Mo., at New London, Mo., June 29.

FRANK THEODORE WEBER, Lewiston, Minn., to Miss Alexia Regina Manel of Ashford, Wis., June 30.

CLIFFORD JOSEPH ORELLETTE, Oconto, Wis., to Miss Katherine Walsh of Rubicon, Wis., recently.

ROBERT CONRAD MOEHLIG, Detroit, to Miss Clara Eleanor Lavelle of Anderson, Ind., June 25.

ARTHUR HENRY ORCUTT, Arcola, Ill., to Miss Helen V. Britman of Brooklyn, July 7.

JOHN ELLAS LIVINGOOD to Miss Minnie E. Janssen, both of Wyomissing, Pa., July 1.

Deaths

John Anthony Murtagh * Col., M. C., U. S. Army; died in the Letterman General Hospital, San Francisco, July 5, from heart disease. He was born in Pennsylvania, June 19, 1856, and was graduated from the Medical Department of the University of Pennsylvania in 1898. Colonel Murtagh entered the military service as hospital steward of the Third Pennsylvania Infantry in 1898; became an assistant surgeon in 1901, five years later was promoted to captain and assistant surgeon. He was made major in the Medical Corps in 1910, lieutenant-colonel in 1917 and colonel, M. C., National Army, Feb. 18, 1918. After the fire and earthquake in San Francisco, in 1906, Colonel Murtagh was in charge of the medical relief.

Henry McLean Cronkhite, Col., M. C., U. S. Army (retired), New York City; Albany (N. Y.) Medical College, 1858; aged 85; who served in the Civil War as a private, was made lieutenant and assistant surgeon in the Army in 1867; was promoted to captain and assistant surgeon in 1870, to major and surgeon in 1886 and was retired in 1895 on account of disability in line of duty and was made lieutenant-colonel, retired in 1904; died in U. S. Army General Hospital No. 1, New York City, June 15, from bronchopneumonia.

Oscar D. Schaeffer, Nazareth, Pa.; College of Physicians and Surgeons, Baltimore, 1886; aged 58; president and general manager of the Nazareth Paper Box Factory; treasurer of the Nazareth Waist Company; director of the Farmers Union Mutual Fire Insurance Company and of the Nazareth National Bank; for about six years postmaster of Nazareth and for a number of years investigator of inheritance taxes for Northampton County; died at his home, July 1.

Eugenie Raura Elisuc, New York City; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1893; aged 53; a Roumanian by birth; treasurer of the American Medico-Pharmaceutical League; lecturer for the New York State Hygiene Society; an authority on psychology and sex hygiene; who was injured in an accident in the Brooklyn Subway in October, 1918, died at her home, July 11.

Willis Oliver Barney, Jr., * Boston; Tufts College Medical School, Boston, 1912; aged 30; a specialist in diseases of the ear, nose and throat; who served as a lieutenant in the United States Naval Reserve Forces, and was relieved from active duty, February 12; died in his apartment in Boston, June 25, from injuries received by being run down by an automobile.

Herman Eichhorn * New York City; College of Physicians and Surgeons in the City of New York, 1904; aged 37; a specialist in gastro-enterology; assistant in internal medicine at the Vanderbilt Clinic and in the neurologic department of the Mount Sinai Hospital; assistant visiting physician to the New York City Children's Hospital; died at his home, July 13.

Daniel Joseph Brown * Springfield, Mass.; Harvard University Medical School, 1886; aged 58; a well known surgeon of western New England; a member of the Springfield Police Commission; chief surgeon of Mercy Hospital for several years; a member of the surgical staff of Springfield Hospital; died at his home, July 8, from nephritis.

Charles Aloysius Obertin, Union Grove, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1904; aged 38; a member of the State Medical Society of Wisconsin; who had been under treatment in a sanatorium in Milwaukee since November, 1918; died at the home of his brother in Milwaukee, July 1, from nephritis.

Amos J. Givens, Stamford, Conn.; Eclectic Medical Institute, Cincinnati, 1889; aged 55; superintendent and proprietor of Stamford Hall Sanatorium; a specialist in the treatment of mental diseases and drug addiction; president of the Fidelity Title and Trust Company, Stamford; died at his home, July 7, from heart disease.

Archibald I. MacLay * Dekavan, Ill.; Jefferson Medical College, 1874; aged 67; division surgeon of the Illinois Central Railroad; for fifteen years a member of the board of education and for several terms city and township health officer; died at his home, July 1, from heart disease.

Robert A. Hildebrand, Glen Rock, Pa.; College of Physicians and Surgeons, Baltimore, 1895; aged 48; a member of the Medical Society of the State of Pennsylvania; who was

taken to York, Pa., for treatment; died in the automobile in front of a physician's office, July 5, from nephritis.

William Reynolds Severson, Los Angeles; University of Illinois, Chicago, 1901; aged 46; a veteran of the war with Spain; who served as captain, M. C., U. S. Army, at Camp Kearney, Calif., and was honorably discharged, March 8, 1918; died in Los Angeles, June 14.

Leslie K. Warren, High Rolls, N. M.; University of Nashville, Tenn., 1905; aged 35; formerly clinical assistant to the chair of surgery in the University of Nashville and University of Tennessee, Nashville; died in the Providence Hospital, El Paso, Texas, July 1.

William Otto Dougherty * Arnold, Pa.; Jefferson Medical College, 1911; aged 34; first lieutenant, Medical Corps, U. S. Army, from March, 1918, until his honorable discharge, March 6, and assistant surgeon at Camp Beauregard, La.; died at his home, June 28.

George James Schuele * Bridgeport, Conn.; Yale University, New Haven, 1908; aged 41; who served as a first lieutenant, Medical Corps, U. S. Army, for a year and was honorably discharged, April 22, 1919; died at his home, July 10, after a surgical operation.

Benjamin Addison McConnell, Dover, Ohio; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; aged 50; a member of the Ohio State Medical Association; died at Union Hospital, Dover, July 9, from disease of the liver.

William Eugene Brandt, Washington, D. C.; University of Louisville, Ky., 1871; Bellevue Hospital Medical College, 1877; aged 70; acting assistant surgeon, U. S. Army, from 1874 to 1877; for many years a government employee; died at his home, June 26.

Jerome E. Moore, Springfield, Tenn.; University of Nashville, Tenn., 1859; aged 87; a member of the Tennessee State Medical Association, who sustained a fracture of the hip in a fall, June 24, died at the home of his daughter in Springfield, June 30.

Mary A. Willis, Jersey City, N. J.; Eclectic Medical College of the City of New York, 1886; aged 74; physician to the Rescue Home for Women and the Children's Paradise, Jersey City; died at her home, July 14, from heart disease.

George Williams Lewis * New Orleans; Tulane University, New Orleans, 1867; aged 72; for several years assistant house surgeon of the Charity Hospital; died at his home, July 4, from bronchial pneumonia.

Henry Tucker Mansfield, Needham, Mass.; Harvard University Medical School, 1869; aged 38; a member of the Massachusetts Medical Society and a veteran of the Civil War; died at his home, July 6.

Edmund Burnard Squire, Auburndale, Mass.; Boston University, 1879; aged 61; a director of the Co-operative Bank of Auburndale; formerly a practitioner in Lyndenville, Vt.; died at his home, June 23.

Charles T. W. Seidel, Jackson Center, Pa.; Western Reserve University, Cleveland, 1884; aged 60; for one term probonotary; died suddenly in Orangeville, June 24, from cerebral hemorrhage.

Allen Evan MacColl, Belleville, Ont.; Queens University, Kingston, Ont., 1891; aged 52; formerly a member of the Ontario Medical College; died at his home, May 5, from arteriosclerosis.

James D. Kiefer, Mount Carmel, Pa.; Hahnemann Medical College, Philadelphia, 1890; aged 59; for many years a member of the local school board; died at his home, July 5, from arteriosclerosis.

Henry T. Rennolds, Baltimore; University of Maryland, Baltimore, 1867; aged 75; a surgeon in the federal service during the Civil War; died at his home, July 5, from senile debility.

Jacob F. Briggs, Shickshinny, Pa.; Pennsylvania Medical College, Philadelphia, 1861; aged 83; also a druggist; a veteran of the Civil War; died at his home, July 6.

Edward Clayton Frost * Campbell, Mass.; Dartmouth Medical School, Hanover, N. H., 1887; aged 59; died at his home, May 5, from tuberculosis following influenza.

Abraham A. Ledbetter, Hallettsville, Texas; Tulane University, New Orleans, 1870; aged 75; died at his home, June 24.

Alvin Nelson Keith, Chicago; University of Illinois, Chicago, 1883; aged 66; died at his home, June 20, from myocarditis.

* Indicate "Fellow" of the American Medical Association.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

DR. MILES' HEART TREATMENT

"Dr. Miles' Heart Treatment" is put out by the Miles Medical Co. of Elkhart, Ind. The history of the exploitation of this preparation is fairly typical of the history of "patent medicines" in general. Before the days of the Food and Drugs Act, when there was no penalty for falsifying on the trade package, it was "Dr. Miles' New Cure for the Heart," and the carton bore the legend:

"DR. MILES' NEW CURE is the Latest and Greatest Discovery for Weak and Diseased Hearts, and the only Safe and Agreeable one known. It is the result of vast experience and years of Scientific investigation by one of the most able and learned physicians of the age."

The trend of the advertising of the "heart cure" can be illustrated by quoting from the descriptive paragraphs in advertising material of various dates:

"Dr. Miles' New Heart Cure: a wonderful, strengthening medicine for weak heart, permanently curing all diseases of the Heart and Circulation."

This later became:

"Dr. Miles' Heart Cure, the greatest heart builder and regulator known."

And still later:

"Dr. Miles' Remedy for the Heart: a strengthening medicine and tonic for the weak heart."

And now is:

"Dr. Miles' Heart Treatment: a strengthening regulator and tonic for the weak heart."

In common with most "patent medicine" advertisements, the "scare" method has been used in exploiting this "heart treatment." The public has been assured for instance, that "one person in every four has a weak or diseased heart" and in some of the older advertising we read under a discussion of the "Treatment of a Weak Heart":

"Unless something is done to check its onward course, it will surely lead to death by the slow torture of some chronic or lingering disorder which it has induced or by the sudden smothering out of life's flame by heart failure."

No information regarding the composition of Dr. Miles' Heart Treatment is vouchsafed by the manufacturers, at least beyond that which the law requires. Thus the labels used since the passage of the Food and Drugs Act admit the presence of 11 per cent. alcohol. Like other "patent medicine" exploiters the makers of this nostrum wish to retain the element of secrecy probably for the mystery that it throws over their products, and for the scope it gives to the imagination of their advertisement writers. Nevertheless they are apparently anxious to capitalize wherever possible any statements regarding the drugs used in their preparation, so the Miles Medical Company publish under the heading "What Medical Authorities Say," some quotations relative to two of the alleged ingredients of the nostrum. Some of these quotations are garbled and modifying clauses have been omitted, while in other cases the quotations are from meretricious sources.

The two drugs alleged to be ingredients of Dr. Miles' Heart Treatment, but not mentioned by name, are digitalis and cactus. It is sufficient to say at this point that careful chemical and physiologic tests have proved conclusively that, if there is any digitalis present it is there in such infinitesimal amounts as not to have the slightest therapeutic effect. Before leaving this phase of the discussion it is worth while to compare one quotation given by the Miles concern as having been given by a medical authority with that of the original. Neither the name of the author, nor the name of the drug is disclosed, however, by the Miles advertising:

AS QUOTED BY MILES

"It is of value in nearly all cases of disease where the condition is one in which the heart fails to do its proper amount of work." (From pamphlet entitled, "What Medical Authorities Say," distributed in Chicago March, 1919.)

THE ORIGINAL QUOTATION

"Digitalis is of value in nearly all cases of cardiac disease where the condition is one in which the heart fails to do its proper amount of work, UNLESS THE FAILURE IS DUE TO UNYACARDIAL DEGENERATION." (From "Practical Therapeutics," A. J. Hare, 1916.)

We have put in small capitals those parts of the quotation from Hare which the Miles Medical Company either omits or modifies. It is worthy of note that the very next sentence in Hare's book, following the quotation just given, reads:

"If simple hypertrophy or excessive compensatory hypertrophy exists, it [digitalis] is harmful." This statement the Miles concern does not quote, although it has in the past recommended the nostrum for cardiac hypertrophy.

To determine the presence or absence of digitalis in Miles' Heart Treatment, a pharmacologist was asked to make physiologic tests with the preparation. The question as to whether or not there is any cactus present was not considered of any special interest, because extensive experimental work has shown that cactus grandiflorus has no physiologic action. The tests that were made by the pharmacologist, however, were such that, had Miles' Heart Treatment contained any drug possessing any heart action, its presence would have been disclosed. The gist of the pharmacologist's report was to this effect:

The tests indicated that there was no digitalis body present in the preparation (in amounts that could have any therapeutic effect) in doses containing enough alcohol to induce narcosis. There was no evidence that Miles' Heart Treatment has any therapeutic effect on the heart aside from that of the alcohol which it contains, even when administered orally, in doses corresponding to those of 1.750 c.c. for a man of 70 kilos. Such doses are equivalent to more than 7 bottles of the treatment. It can be said with certainty that Miles' Heart Treatment does not exert any action which entitles it to be considered as belonging to the digitalis group, or to any other group recognized by clinicians as exerting any typical, demonstrable, pharmacologic action on the heart.

In addition to the pharmacologic tests, Miles' Heart Treatment was also subjected to chemical analysis in the A. M. A. Chemical Laboratory. A summary of the chemist's report follows:

CHEMIST'S REPORT

"Chemical examination shows Miles' Heart Treatment to be a solution of a compound, or compounds, of iron repre-

Greatly reduced reproductions of the carton of "Dr. Miles' Heart Treatment" through varying stages of truthfulness.

senting about 0.120 gm. metallic iron in 100 c.c., or about $\frac{1}{2}$ grain in one fluidounce. There is also a small amount of phosphate, about 5 per cent. glycerin, a reducing substance, which may be glucose or invert sugar. No potent alkaloidal drugs could be detected. The presence of an ammonium compound was demonstrated by the liberation of free ammonia on addition of fixed alkali to the preparation. The liquid is colored with caramel. A solution of iron glycerophosphate in 10 per cent. alcohol with about 5 per cent. glycerin and a little sugar or glucose had much the same chemical properties as Miles' Heart Treatment.

How long would the "patent medicine" business last if the exploiters of these nostrums were required to publish a full quantitative formula of the active ingredients on the label, and, further, were required to tell the truth about their products? The "Latest and Greatest Discovery for Weak and Diseased Hearts," which was "the result of vast experience and years of Scientific Investigation by one of the most able and learned physicians of the age" does not loom as imposingly after it has been subjected to the test of independent chemical and physiologic investigation. A little iron, a small amount of phosphate, about 5 per cent. of glycerin, and 11 per cent. of alcohol, the mixture colored with caramel—a great discovery indeed!

REQUEST FOR BIOGRAPHIC DATA

To the Editor:—In revising my "Cyclopedia of American Medical Biographies" into a wholly new cyclopedia, in cooperation with Dr. Walter L. Burrage, and in adding some hundreds of names, there remain a certain number of physicians about whom we have not been able as yet to obtain needed information. I write to THE JOURNAL to ask if any of its readers can enlighten me, and if they will not kindly at once communicate with me by letter that I may complete the following biographies:

In the first place, is Dr. S. S. Herrick, eminent chemist and sanitarian of New Orleans still living? If not, when and where did he die? Is Dr. D. B. Hoffman, who wrote the "Medical History of San Diego County, California," born in 1827, still living? The same question I am compelled to ask regarding Frederick V. Hopkins, early geologist of Louisiana. One of the most important of all my biographies is that of William Anderson, who lived for a time in New York, wrote a fine "Surgical Anatomy of the Groin" in 1822, and in 1837 suggested a hospital in connection with a university of the city of New York. He was associated with Valentine Mott and Wright Post in his activities. He probably graduated in Scotland, and probably returned there.

I want in all the foregoing cases the birth, death, anything about the early life, professional accomplishments and activities of any of the gentlemen, and any reference to any published memoranda, and shall be truly grateful to any one who will help me out immediately.

HOWARD A. KELLY, M.D.
1418 Entaw Place, Baltimore.

"METABOLISM IN PERNICIOUS ANEMIA"

To the Editor:—I would be obliged to you if you will correct the impression that you give in your editorial with this title (June 21, 1919, p. 1840) regarding our "Studies of the Chemistry of Pernicious Anemia." We did not investigate the metabolism of substances in this disease but were careful to point out that our studies were directed rather at certain general chemical investigations than to anabolism and catabolism phases. We paid no attention to the intake of food, so far as its exact chemical composition was concerned. We only stated as part of the sixth conclusion that "there is a rate of suboxidation the neutral sulphur fraction is increased," which statement is, of course, correct. But we laid no stress on this matter in the paper, and we only mentioned it casually. Our object in this research was to study the functional capacity of the various organs. You misquote

us and destroy the value of our contribution to this subject by stating that the functions of the liver are reported as undamaged. We state (Conclusion 8) that "there is a deficiency in the hepatic detoxication function as shown by the sulphoconjugation test." We wrote our paper mainly to impress this finding for we believe that this may be the causative factor of this disease: the failure of the liver to neutralize the poisons generated in the gastro-intestinal tract, resulting in the absorption of these poisons by the blood with the resulting blood destruction.

MAX KAHN, M.D., New York.

"PROTEOGENS"

STATE OF OHIO, STATE DEPARTMENT OF HEALTH.

To the Editor:—I note in the issue of THE JOURNAL for July 12, a statement regarding the so-called "Proteogens" manufactured by the Wm. S. Merrell Company of Cincinnati.

My attention has been called to the fact that salesmen of this company have been exhibiting a letter purporting to show that this department has endorsed their products in the treatment of venereal diseases. The letter in question was written by a physician employed in one of the clinics conducted jointly by this department and the U. S. Public Health Service, and the stationery of the department was used without authority. The physician in question has made numerous efforts to recall the letter, but the Merrell people profess an inability to control its use.

I need not add that this department has not endorsed and will not endorse these products, and has no evidence that they are of any value whatsoever.

ALLEN W. FREEMAN, M.D., Commissioner of Health.

"THE NEUROLOGY OF CERVICAL RIBS"

To the Editor:—Dr. Church, in his paper on "The Neurology of Cervical Ribs" (THE JOURNAL, July 5, 1919, p. 1), says: "No textbook on nervous diseases makes the slightest detailed mention of cervical ribs in connection with brachial plexus disorders," etc. In the second edition of Jelliffe and White, Diseases of the Nervous System, 1917, is a discussion of the subject, and (p. 366) a roentgenogram with the caption: "Double cervical rib causing mixed type of brachial palsy." In several places the relation of cervical rib to brachial plexus disorders is given in detail. Dr. Church further states that cervical ribs have never been observed in the first, second or third ribs. In the textbook just mentioned will be found in the section on cervical rib (p. 378): "Thomas Murphy has recorded a case in which the symptoms were due to the pressure of the first rib. A similar case is reported by Sherren."

SMITH ELY JELLIFFE, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE SEPTIC VIBRIO

To the Editor:—I am a discharged soldier about to enter the state university this fall. Across the ocean, during my stay as a patient in a hospital, I heard of a parasite known as the *Vibrio septicus*, and cannot seem to get any definite information as to its character or morphology. Will you kindly give me any information you may have available?

H. G. WELLS, Waterbury, Vt.

ANSWER.—The *Vibrio septicus* (*Bacillus septicus*, *B. oedematis*, bacillus of malignant edema) was discovered by Pasteur in 1876. The next year, 1877, Pasteur and Jonbert (*Bull. de l'Acad. de méd.*, 1877:793) established the principal characters of the vibrio and called the sickness produced by it acute experimental septicemia. Koch and Gaffky (*Mitt. a. d. k. Gesundheitsamt*, 1881, p. 52 et seq.) gave it the name, bacillus

of malignant edema. Mice and guinea-pigs are exceedingly sensitive to it. Chauveau and Arloing discovered about 1884 that *Vibrio septique* was the cause of gas gangrene in man. The traumatic gangrene of some animals is also due to it. The organism is about the size of the anthrax bacillus (7 by 0.8 microns) but narrower, and the ends are not so square cut. It is gram-negative unless the staining with gentian violet is prolonged. It thrives well on culture mediums. It kills a guinea-pig in two days. Although it is considered to be the cause of gas gangrene it is not the sole cause, for *B. phlegmonosus-emphysematosus* of Frankel and *B. aerogenes-capsulatus* of Welch and Nuttall produce it also, as well as other germs. For further details one may consult any good textbook on bacteriology.

STRENGTH OF EPINEPHRIN FOR LOCAL ANESTHESIA

To the Editor:—Please give me the following information:

1. What strength of epinephrin (adrenalin) should be used in injecting tonils for local anesthesia?
2. What are the dangers of strong solutions of epinephrin, aside from the secondary hemorrhage?
3. Would 1 dram of 1:1,000 solution of epinephrin to the ounce of 1:500 cocaine, and using 2 drams in each tonsil, be dangerous?

Please omit my name. B. E. M.

ANSWER.—1. From 10 to 15 drops of the 1:1,000 solution of epinephrin per ounce of anesthetic solution is the strength usually employed.

2. The chief danger of strong solutions lies in the possibility of injecting it inadvertently into a vein, in which case 1 c.c. of a 1:1,000 solution might produce most alarming and even fatal results from overwhelming effect on the circulation. In subcutaneous infiltration, there is the additional danger of necrosis from excessive vasoconstriction; but this probably does not apply to as vascular a tissue as that of and around the tonsil.

3. The addition of 1 dram of a 1:1,000 solution of epinephrin to the ounce of 1:500 cocaine would probably not be very dangerous; but the concentration is greater than that usually employed; and, when the solution is used as freely as 2 drams per tonsil, it might not be entirely devoid of danger.

PROTECTION OF BOOKS AGAINST INSECTS

To the Editor:—I should like to know a way to protect my library against the insects that are now destroying it. I have used without success powdered pepper, "Noflaine" and formaldehyd fumigations.

PENRO POSS, M.D., Batabanó, Havana, Cuba.

ANSWER.—Powdered pepper and formaldehyd fumigations have practically no effect on insects attacking libraries. The U. S. Bureau of Entomology recommends fumigation of the library with hydrocyanic acid gas, or the placing of the books in a tight container, such as a wooden box well lined with paper, and fumigation with carbon disulphid. Proper precautions must, of course, be taken, especially in using hydrocyanic acid. Both these substances can be obtained in Cuba. Instructions (in English) for applying them will be found in Farmers' Bulletins 699 and 799, and might perhaps be obtained also in Spanish from the Department of Sanitation, Havana, Cuba.

ARMY DISCHARGE PAPERS

To the Editor:—In the discharging of medical officers from Army service, the only homelike discharge received by many was an order stating that for "convenience of the government," the following named will be discharged. Then follows a long list, including the officer to whom the communication is addressed. Will this be the only discharge given such men?

C. M. MCKRELL, M.D., Matherville, Ill.

ANSWER.—The language used in the discharge notice is that prescribed by the War Department, except that when only one individual is discharged at a time his name is inserted in the body of the order instead of at the end. In addition to this order each officer discharged is entitled to a formal discharge certificate. These certificates were not authorized until December, 1918; it was provided at that time that those who had not been given the certificate could obtain it by application to the Adjutant-General of the Army.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALASKA: Juneau, Sept. 2. Sec., Dr. L. P. DAVES, Juneau, Alaska.
HAWAII: Honolulu, Sept. 9-11. Sec., Dr. J. R. Judd, Honolulu, Hawaii.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Dr. Cias. DUNCAN, Concord, New Hampshire.

New York March Examination

Mr. George M. Wiley, director, Examinations and Inspections Division, reports the written examination held at New York City, March 11-14, 1919. The examination covered 8 subjects and included 10 questions. An average of 75 per cent. was required to pass. Of the 148 candidates examined, 134 passed and 14 failed. The following colleges were represented:

College	PASSED	Year Grad.	No. Licensed
Bennett College of Eclectic Med. and Surg.	(1907)	1
Harvard University	(1919)	1
Columbia University, Coll. of Phys. & Surg.	(1919)	51
Fordham University	(1917) (1919)	48
New York Homeo. Med. Coll.	(1917)	1
University and Bellevue Hosp. Med. Coll.	(1919)	31
FAILED			
Tufts College	(1917)	1
Columbia University, Coll. of Phys. & Surg.	(1919)	4
Fordham University	(1919)	2
University and Bellevue Hosp. Med. Coll.	(1919)	6
Medical College of Virginia	(1915)	1

Dr. Wiley also reports that between March 25 and May 1, 1919, 6 candidates were licensed by endorsement of their credentials. Of these one was granted a reregistration license, 3 were granted diplomas by reciprocity with other states, and 2 were licensed by endorsement of their diplomas on the basis of eminence and authority in the profession. Of those licensed by reciprocity and endorsement of credentials the following colleges were represented:

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
New York Homeo. Med. Coll.	(1919)	New Jersey
Woman's Medical College of Pennsylvania	(1916)	New Jersey
ENDORSEMENT OF DIPLOMAS			
Kentucky School of Medicine	(1899)	
Harvard University	(1886)	

Minnesota April Examination

Dr. Thomas S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral and written examination held at Minneapolis, April 1-3, 1919. The examination covered 15 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 18 candidates examined, 13 passed and 5 failed. Eleven candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per. Cent.
Georgetown University	(1913)	82.2
University of Illinois	(1919) 89.1, 89.5, 91.	
Harvard University	(1913) 94.3; (1918) 95.5; (1919)	92.6
University of Minnesota	(1918)	92.8*
Albany Medical College	(1905) 78; (1911)	87.9
Columbia University Coll. of Phys. and Surg.	(1918)	89.2
Cornell University	(1911)	93
Miami Medical College	(1900)	88.3
University of Pennsylvania	(1917)	85.5

College of Medicine and Surgery, Physio-Medical, (1909) 66
University College of Medicine, Kelowna, (1909) 64
Montreal College of Medicine and Surgery (1908) 61
*Granted M.D. degree in 1918 after completing four year course; will receive M.D. after completing his intern year.

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
American Medical Association College	(1904)	Illinois
Chicago College of Medicine and Surgery	(1917)	Illinois
Rush Medical College	(1905) North Dakota	Illinois
University of Illinois	(1914)	Wisconsin
University of Michigan Medical School	(1916)	Michigan
University of Minnesota	(1902)	N. Dakota
Long Island College Hospital	(1910)	N. Dakota

Book Notices

JOHN COAKLEY LETTSON AND THE FOUNDATION OF THE MEDICAL SOCIETY. Being the Presidential Address Delivered Before the Medical Society of London on October 8th, 1917. By Sir St. Clair Thomson, M.D., F.R.C.P., F.R.C.S. Paper. Price, two shillings and sixpence. Pp. 63, with illustrations. London: Harrison and Sons, 1918.

The Medical Society of London was organized in 1753 by Dr. John Coakley Lettson, the physician on whose name was written the historic doggerel which has so often been quoted as expressing the attitude of some of the medical profession,

"When any sick to me apply,
I physicks, bleeds, and sweats 'em;
If after that they choose to die,
What's that to me, I. LETTSON."

Sir St. Clair Thomson, one of our foreign guests at the Atlantic City Session, president of the Medical Society of London for 1917 and 1918, took as the subject of his presidential address the life and character of his first predecessor in office. The address is published in pamphlet form and is a fascinating biographic study of professional life and conditions in England from 1750 to 1815. Although born in the West Indies and early left an orphan without friends or influence and very little money, Lettson in 1766 settled in London at the age of 20 and in a short time developed a practice and professional standing that placed him at the head of his profession by the time he was 40. His biographer states that his income from 1786 to 1800 ranged from five thousand to twelve thousand pounds a year, or practically \$25,000 to \$60,000. The successful medical practitioner led quite as strenuous a life then as now. In 1791, at the age of 47, he says, "During the last nineteen years, not one holiday have I taken." In another letter he complains that his practice had not suffered him to sleep in his own bed for thirteen nights. That he was a systematic and tireless worker is shown by his voluminous correspondence which, of course, in those days was carried on entirely by hand. At one time he had more than two hundred correspondents on professional, scientific and personal matters. Nearly all of his letter writing was done in his carriage. His outside interests were quite as extensive and absorbing as his professional work. In 1770, he founded the first general dispensary in London. In 1773, he organized the London Medical Society. He was an active member and lecturer of the Royal Philosophical Society, and one of the founders of the Royal Humane Society. He was a personal friend and supporter of Edward Jenner, and an ardent advocate of vaccination. His personal friendship for John Howard led him into much activity for prison reform. He was during his entire life deeply interested in botany, agriculture and fossils. He organized soup kitchens, wrote tracts, delivered lectures on the effects of hard drinking, cultivated bees, formulated plans for the management of boarding schools with special regard to diet, clothes, games and sanitation, and was greatly interested in the history of medicine. In 1801, he published three volumes of essays in which appear discussions of such subjects as poverty, prostitution, the education of the blind, the treatment of the deaf and dumb, the prevention of hydrophobia, and the use of substitutes for wheat in making bread. The last subject became one of public interest and importance during the Napoleonic wars, just as it has been during the late world war. Not only did the price of bread rise, but also the quality and size of the loaf diminished. Lettson recommends Indian corn, potatoes, rice and other substitutes for wheat bread. Especially interesting are his relations to the United States. Benjamin Rush was an intimate friend, and in a book of memoirs published in 1817, it appears that a large tract of land on the Susquehanna River belonging to Dr. Rush was named after Dr. Lettson. He first sent Jenner's vaccine lymph across the Atlantic, assigning it to his friend, Dr. Waterhouse, professor of medicine at Harvard University. His correspondents included Washington and Benjamin Franklin. Harvard University in 1790 gave him the degree of LL.D. He was an honorary member of the medical societies of New York, Massachusetts and Philadelphia, of the Massachusetts and Philadelphia Humane Societies, of

the Pennsylvania Society for the Abolition of Slavery, and of practically all the scientific and historical societies that then existed in America. His work, which increased as he grew older, lasted almost until the day of his death, which occurred in his seventy-first year after an illness from pneumonia of only a few days.

This biographic sketch is a historical document of great interest and fascination, giving with unusual vividness a picture of professional life of a century and a half ago. It is charmingly written and copiously illustrated.

SURGERY IN WAR. By Alfred J. Hull, F.R.C.S., Lieut.-Col., Royal Army Medical Corps. With a Preface by Lieut.-Gen. T. H. J. C. Godwin, C.B., C.M.G., D.S.O., Director-General, Army Medical Service. Second edition. Cloth. Price, 86 net. Pp. 624, with 210 illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

There are today, roughly speaking, four classes into which current medical literature may be divided: In the first group we may assemble the so-called research papers which deal with theories and phenomena in the field of the medical sciences from the standpoint of their truth or falsity. In a second group we may assemble papers of the nature of case reports, presenting the result of practical experience and, in a growing percentage of cases, justifying the term "clinical research" which has been applied to the type of work they represent. In a third group we find those books and monographs which treat of their subject from the standpoint of the principles involved, omitting detailed analyses, giving a bird's-eye view, so to speak. In the fourth group we find the so-called books of reference, in which great attention is paid to that detail and close analysis which works of the preceding group seek to condense and formulate into broad generalizations. It is in this group that we should place the book under discussion. Bearing in mind the author's statement: "The object of this book has been to give members of the profession who have not practiced war surgery an account of the treatment which has proved efficacious in our hands. Symptomatology and details of treatment, which are found in textbooks of general surgery, have not been repeated. The book is not intended to be in any sense complete. Surgical knowledge is presupposed, and our efforts have been mainly directed to recounting methods of treatment of the more common injuries met with in war," we are inclined to credit the author with underestimating the value and scope of his work. If we were to offer adverse criticism, it would deal with the illustrations. There are numerous sketches accompanying the text. The book would present a much more finished, workman-like appearance if the majority of the sketches had been submitted to a capable artist for revision before publication. Secondly, it seems to be almost inexcusable that a publisher should permit the appearance of a high grade book, such as this, with a full page illustration turned upside-down. Apparently the publishers are feeling the pinch of the universal shortage of labor. In spite of this slight mechanical disability, "Surgery in War" is one of the best books on the subject that we have seen.

THE EARLY TREATMENT OF WAR WOUNDS. By Colonel H. M. W. Gray, C.B., C.M.G., M.B., Consultant in Special Military Surgery. Cloth. Price, \$3.75. Pp. 269, with 25 illustrations. New York: Oxford University Press, 1919.

One of the greatest difficulties with most authors writing on medical subjects is that of stating their problem and its solution without a great deal of unnecessary exposition, and without dragging in a whole family of distantly related and entirely superfluous matters. In this book, Colonel Gray has overcome the difficulty, and presents the essential facts with refreshing simplicity and vigor. He does not write from the standpoint of a man with a theory to prove; rather, as one reads the book, the impression grows that here is an earnest, scientific surgeon of wide experience endeavoring to tell the simple truth without bias and, incidentally, without that "holier than thou" attitude which the advocates of particular plans of treatment are so prone to adopt. The first six chapters deal with the general management of the wounded, the essentials of first aid, the treatment of shock, the use of antiseptics and dressings, and the principles of the operative treatment of war wounds, great stress being

laid on the early and complete excision of devitalized tissue as a fundamental in the prevention of wound sepsis. The remaining five chapters deal with the treatment of wounds of special regions, considering in particular wounds of the brain, the thorax, the spinal cord, compound fracture of the femur, and wounds of joints. Abdominal wounds are not given consideration. The author says: "I have not written anything on abdominal wounds. It has always seemed to me that a surgeon who has mastered the technic of successful excision of an ulcerating cancer of the colon is capable of obtaining as good results as possible if he applies the same principles in the treatment of war wounds of the abdominal organs coupled with those used in combating spreading peritonitis." This volume deserves a place on the shelves of every medical library.

Contributory Negligence and Evidence in Malpractice Case

(*Summers v. Tarpley* (Mo.), 208 S. W. 2d, 266)

The Springfield (Mo.) Court of Appeals, in reversing a judgment obtained by the plaintiff for \$500 damages for alleged malpractice, and remanding the case for a new trial, says that, in jumping from a vehicle on account of the team's running away, the plaintiff broke the small bone of her left leg about 3 inches above the ankle, and fractured the larger bone near the ankle joint. The defendant who, the record showed, was what is commonly called a "country doctor" and was not equipped for accurate diagnosis, diagnosed the injury as a dislocation. He testified that he put the disarranged parts back in position to the best of his judgment, bound the leg with ordinary bandage, covered it with cotton, and strapped it in a metal splint. This splint was taken off at the end of seven days. About fifteen days after the injury, he first realized that the bones were broken, and put the splint back on. The bones were not put in proper apposition, however, and the result was a somewhat deformed ankle. He gave as an excuse for not diagnosing more thoroughly in the first instance that the plaintiff's father and mother would not permit him to administer chloroform, claiming that the plaintiff had a weak heart. The defendant also testified that he insisted on the family's getting another physician to aid him, which they declined to do, and again declined to do when, at the end of the fifteen days, he realized that the bones were broken and asked for another physician to help him. He said that he did in both instances the best he could under the circumstances. The evidence for the plaintiff, on the other hand, tended to show that the defendant no time made a request for assistance, but insisted all the time that the injury was only a dislocation, and that he did not need any assistance.

The plaintiff not having charged in her petition that her deformed ankle was due to the defendant's lack of skill, but was due to his unskillful and careless treatment, there was no error in the trial court's refusing to permit him to prove his general reputation as a skillful physician.

Nor was there error in an instruction to the jury to the effect that the burden was on the defendant of proving to the reasonable satisfaction of the jury by a preponderance of the evidence the defense of contributory negligence, the court being of the opinion that the evidence offered by the defendant tending to establish that the plaintiff's deformed ankle was due to her own negligence and that of her family in failing to procure assistance was the defense of contributory negligence pure and simple. It will be observed that the defense of negligence on the part of the patient is, in a malpractice case, called contributory negligence as in any other kind of case. It is clear that the alleged negligence of the plaintiff in this case, if established, would constitute a complete defense, and this court knows of no other term than "contributory negligence" to designate that character of defense. Contributory negligence as a defense in malpractice cases is recognized by all authorities, but some differ as to the effect of negligence of the patient after operation or treatment in failing to observe the directions of the physi-

cian. But the court holds it was reversible error to permit physicians called on behalf of the defendant to be asked, on cross-examination, if they ever treated a patient that was left in that condition by similar injury, having reference to the condition of the plaintiff's ankle. It was improper cross-examination, and prejudicial. Aside from the force of the situation tending to elicit a negative or noncommittal answer, the plaintiff would be establishing that the defendant was negligent by proving what some other physician had or had not done. If a physician under such circumstances should answer in the affirmative, then a defendant, situated as in the case at bar, would be entitled to have the physician explain. He could go into all the details of the collateral case, which would lead far afield from the issues, and into matters wholly irrelevant.

Evidence of Fraud by Itinerant Doctor in Obtaining Note

(*Security State Bank of Wichita v. Seaunier* (Kan.), 178 Pac. R. 239)

The Supreme Court of Kansas, in reversing a judgment obtained by the plaintiff bank, and ordering a new trial, in this action on a promissory note given by the defendant to one Slocum, says that the latter was an itinerant doctor who advertised his business by a dog, pony and medicine show. On the day on which the note was given, Slocum told the defendant that his wife had catarrh, and that a cancer was forming in her stomach; that if the defendant did not do something for her within thirty days, she would be past doing anything with at all; that, if she was not treated in the right way, she would die within thirty days; and that she ought to go to a hospital; that he had an institute and hospital at Wichita, but that he could treat her at her home. He asked the defendant if he was little enough to let his wife lay and die for \$120. He promised the defendant to keep the note for six months, and said to him that his wife would be well; that the medicine he would give would cure her; and that he could cure her in sixty days. Immediately after obtaining the note, he tried to sell it in Neodesha, and soon thereafter transferred it to the plaintiff. He had neither institute nor hospital in Wichita. The defense was that the note had been obtained by fraud and was without consideration, and that the plaintiff had purchased the note in bad faith and with knowledge of the fraud.

The defendant's first assignment of error was that the trial court erred in refusing to permit him to introduce in evidence certain chattel mortgages on Slocum's show outfit to secure the payment of certain debts then owing by Slocum to the plaintiff, and to secure any other indebtedness that might be incurred to the bank by Slocum. There were four of those mortgages. They were signed by Slocum and by his wife, who claimed to be the owner of the property. The mortgages should have been received in evidence to establish links in a chain of circumstances which would tend to show that Slocum had committed a fraud on the defendant, and that the bank had knowledge of that fraud and was not a holder of the note in good faith.

The defendant's second assignment of error was that the court erred in rejecting the depositions of four physicians of Wichita. The testimony disclosed in those depositions concerned the honesty and integrity of Slocum, and his reputation and ability as a physician. That evidence tended to establish another link in a chain of circumstances which might prove that Slocum was guilty of fraud in procuring the note, and should have been admitted for that purpose.

The trial court placed the burden of proof on the defendant, and, after his evidence had been introduced, sustained a demurrer thereto, and instructed the jury to return a verdict in favor of the plaintiff. But the evidence of what occurred when the note was given, together with the chattel mortgages and the testimony contained in the depositions, if the chattel mortgages had been admitted in evidence, would have been sufficient to compel the trial court to submit the cause to the jury for the purpose of determining whether Slocum had been guilty of fraud in obtaining the note; and a finding of the existence of fraud would have been sufficient to place on the plaintiff the burden of showing that it acquired the note in due course.

AMERICAN PEDIATRIC SOCIETY

Thirty-Fifth Annual Meeting, held in Atlantic City, N. J., June 16-18, 1919

(Concluded from page 229)

Cerebrospinal Involvement in Hereditary Syphilis

DR. C. P. JEANS, St. Louis: About 30 per cent. of syphilitic infants show changes in the cerebrospinal fluid of such a character and degree as to make the diagnosis of syphilitic involvement of the nervous system quite certain. There may or may not be associated clinical manifestations indicating neurosyphilis. Intravenous and intramuscular treatment will result in most instances in the disappearance of the abnormal findings, both in the cerebrospinal fluid and in the blood. Routine spinal puncture in older children having either latent or active syphilis likewise showed evidence of neurosyphilis in about 30 per cent. of those examined. Prolonged intravenous or intramuscular treatment will eventually result in a negative blood Wassermann reaction, while the cerebrospinal fluid may or may not continue to show changes indicating neurosyphilis. Intraspinal treatment will cause the disappearance of pathologic changes in the spinal fluid when these have persisted.

DISCUSSION

DR. W. McKIMM MARRIOTT, St. Louis: Dr. Jeans' experience is that the administration of arsenic before mercury has been given may result in a serious reaction, namely, the Herxheimer reaction. In order to avoid this reaction, treatment should be given first with mercury and later with arsenic. A further practical application of the results of Dr. Jeans' work is that if one watches the spinal fluid in cases that are apparently cured, and after the blood has become negative, the spinal fluid may still be positive.

DR. L. R. DE BUYS, New Orleans: It is well to sound a warning against being too eager to exclude congenital syphilis in the presence of a negative blood Wassermann test. One should always examine the cerebrospinal fluid when syphilis is suspected. It is also well to get away from the intraspinal method of treating these cases.

DR. ISAAC ABB, Chicago: What is your manner of administering arsenphenin? I use both mercury and arsenic.

DR. C. P. JEANS, St. Louis: We use the arsenobenzol brand of arsenphenin. We also inject mercuric chloride, one-half minum per kilogram, of a 1 per cent. solution.

Predominance of Seborrheic Eczema in Early Life

DR. THOMAS S. SOUTHWORTH, New York: The part played by seborrhea in the causation of eczema has been overlooked. The seborrheic factor may be traced in the milder forms on the face and body, the identity of which may be established by finding seborrhea on the scalp and in the characteristic locations in the folds above and below the ear. A seborrheic basis may furnish the starting point for an eczema. The recognition of a seborrheic basis for a lesion by no means excludes the possibility of other micrococcic invasion. There is no conflict between a seborrheic and an anaphylactic or toxic etiology of eczema, since seborrheic neighborhoods are susceptible to other superadded conditions of the skin. Zinc oxid ointment, so helpful in other types, is useless by itself in seborrheic cases, even of the simplest form, unless ammoniated mercury or tar or resorcin is added to destroy the micro-organisms present. The dietetic factor in these cases must be differentiated and corrected before these cases will yield to treatment.

Aneurysm of Ascending Arch of Aorta in a Thirteen Year Old Boy

DR. HENRY HERMAN, New York: Physical examination showed marked pulsation of the carotids, the heart enlarged, particularly to the left, rather a wide area of dullness at the level of the first and second interspaces, and a systolic murmur. The electrocardiogram showed a marked ventricular predominance. The fluoroscopic examination revealed an aneurysm of the ascending arch of the aorta. The roentgen ray corroborated this finding. The Wassermann test was + + + +. The mother's Wassermann test was also + + + +. In the epigastrium there was a hard mass, about 6 cm. in diameter, extending down about 8 cm. from the ensiform, not tender, and probably a gumma. The spleen was markedly enlarged, extending to the iliac crest. There were no palpable epitrochlear glands. The reason for presenting this case is the great rarity of aneurysm of the thoracic aorta in children, there being only about twenty cases of aneurysm of the aorta in children reported in the literature.

Congenital Disseminated Atelectasis

DR. JOHN RUHRÄH, Baltimore: When first seen, Nov. 15, 1917, the child, then between 4 and 5 months of age, showed cyanosis and rapid respiration, the respirations being rarely under 50 a minute and often 75 and 80. The heart was normal so far as could be ascertained. The roentgen ray revealed disseminated patches of unexpanded lung. The child, with proper care and attention to feeding, gradually improved, and at present is apparently normal.

Case of Scorbatic Hematuria

DR. PERCIVAL J. EATON, Pittsburgh: This case occurred in a rather poorly nourished child fed on patent foods and then on cooked foods, but never on fresh, raw food. The child's condition seemed to point more toward scurvy than toward calculus, and the urine showed nothing abnormal except bright red blood. Fresh raw milk, beef juice and orange juice were prescribed. Under this treatment the hematuria disappeared, and it was not necessary to use the sound.

Anomaly of the Diaphragm with Gastric and Intestinal Obstruction

DR. L. R. DE BUYS, New Orleans: This baby was perfectly well up to the age of 3 months, when she had a peculiar attack of colic with twisting and straining. After several attacks of this nature the child became acutely ill, with high temperature and rapid pulse. On examination the chest showed less movement of the left side and was apparently not as full as on the right side. Resiliency was absent. The heart was displaced to the right, the apex beat being in the median line. The abdomen presented a tumor in the epigastrium and left hypochondriac region, lying transversely, and about the roundness of a banana, 3 or 4 inches long, and distinct from the lower border of the ribs. The blood examination disclosed a leukocytosis of 29,500, with 88 per cent. polymorphonuclears. The roentgenogram suggested an intussusception. An operation, performed for the relief of the constriction, revealed a diaphragmatic hernia. The intestine was found empty and contracted. No omentum was visible. When the tumor was palpated there was a sudden gush of blood from the mouth and nose and a cessation of breathing. Attempts at resuscitation were futile. A further incision showed the spleen lying on top of the tumor with its long axis transverse to the abdomen and its convex surface lying next to the diaphragm, the lower end being just under the costal arch. The tumor was attached to the hilum of the liver. The transverse colon was not in sight. There was a hiatus in the diaphragm under the tumor which was found to be continuous with another fluid mass in the thorax. On opening the left chest, the fundus and greater part of the body of the stomach, the transverse colon and the great omentum were found in the thoracic cavity. No pleura was found over these viscera. The tumor consisted of the pyloric portion of the stomach twisted on its axis at the hiatus behind the diaphragm. At a second necropsy, the left suprarenal body was found to be enlarged and hemorrhagic. At the posterior left half of the diaphragm there was no attachment; a hard cord bridged over this area in a dome-like manner. There was another twist in the stomach anterior

to the pyloric orifice. The two twists in the stomach had cut off certain blood supplies which resulted in gangrenous necrosis of the stomach wall. Among the points of interest in this case were the absence of tenesmus and bloody stools in an obstruction involving the descending colon, which would require the exclusion of the diagnosis of intussusception, and the roentgenogram without evidence of air in the thorax, especially with an intestinal hernia into it.

Incidence and Significance of Rheumatic Nodules in Children

DR. JOSEPH BRENNEMANN, Chicago: Rheumatic nodules are as frequent in children in this country as they are in England, where they have received so much attention. Observers should settle the question as to whether these nodules are a definite quantitative accompaniment of rheumatism or whether they have a selective geographic habitat. They practically never occur in rheumatism uncomplicated by endocarditis or pericarditis. They are relatively rare in mild cases of rheumatism or chorea with cardiac complications, but occur with great regularity and usually very abundantly in chronic or recurrent and active endocarditis, especially in those patients that for weeks or months sway between life and death, not alone because of broken compensation, but even more because of a smouldering uncontrollable infection that ever and anon lights up again. As rheumatic nodules are pathognomonic of rheumatism with carditis, they are often of considerable diagnostic value. A new and abundant crop has often an ominous significance in showing that a new and serious cardiac invasion has taken place. Rheumatic nodules, unless very carefully looked for, are likely to be overlooked. Careful search will reveal them more often than is commonly thought.

AMERICAN SURGICAL ASSOCIATION

Fortieth Annual Meeting, held at Atlantic City, N. J., June 16-18, 1919

(Concluded from page 222)

Thoracic Fistula and Chronic Empyema: Nondeforming Operation for Its Cure

DR. HOWARD LILIENTHAL, New York: Thoracoplastic collapsing operations for the cure of sinuses and pneumothorax following empyema are, as a rule, unjustifiable and unsurgical. Not only is there permanent thoracic asymmetry, but the affected lung is permanently deprived of much of its function. The method I use restores the lung almost to its normal capacity, while its danger is far less than that of the Schede, Estlander and Delorme operations. The operation consists in the approach through a long seventh interspace incision beginning behind the costal angle and extending almost or quite to the cartilage. From one to four ribs are divided upward or sometimes downward at the posterior angle of the wound, or very rarely upward at its anterior end in order to expose every recess of the cavity. A powerful automatic rib retractor is an absolute necessity in this operation. The lung, which will be found bound down by adhesions, is now liberated by incision through the confining membrane, which may be removed if there is an easily found line of cleavage and which otherwise may be loosened by numerous intersecting incisions. By intrapleural insufflation the lung is expanded and it should reach the chest wall. Fine bubbling on the surface is of no consequence, but whistling means that a bronchus has been entered, an accident which should, if possible, be avoided. Drainage is secured through the original sinus enlarged for the purpose, the new surgical wound being closed by interrupted sutures of chronic catgut through the muscles, but without pericostal sutures. The skin wound is approximated by silk or silk-worm-gut. The after-treatment consists in dressings, irrigations and strenuous blowing exercises.

Delayed or Late Extraction of Intrathoracic Projectiles by Method of Petit De La Villéon

DR. ROBERT G. LECONTE, Philadelphia: This method depends on the localization of the projectile with regard to its anatomic surroundings in contradistinction to its mathe-

matical situation from surface markings. The projectile is removed by sight with forceps through a small button-hole opening, with the employment of the roentgen rays and a fluoroscopic screen.

DISCUSSION

DR. ANTOINE DEPAGE (through Dr. Joseph Van de Velde): In a bad case of empyema after using the Carrel method and making a bacteriologic count, the wound became sterile. Then we simply closed the wound and the result was perfect. All cases treated in this way gave very good results. Before suturing, it is very important that the bacteriologic count should be satisfactory and that there should be no secretion in the wound. The edges of the wound should be freshened, the pleura and the skin then being sutured. In a large cavity the fluid will do no harm since it is absorbed gradually.

DR. ALEXIS V. MOSCHOWITZ, New York: The essential elements in the treatment of empyema are the sterilization of the cavity and the work Nature will do following this.

DR. WILLY MEYER, New York: The reference to the aid which Nature will give in the treatment of empyema recalls a case of a child, 10 months of age, in whom the formaldehyd glycerin injections were used. Much to my surprise the sinus closed; the roentgen ray revealed a pneumothorax, but at the end of two weeks the child was entirely well. I was called on some time ago to remove the bismuth oil which had been injected in an old empyema case to determine the extent of the cavity, and in which acute bismuth poisoning had resulted. We reopened the original resection of the rib. The man continued to have irregular temperature and we instituted the Carrel-Dakin treatment. After forty-eight hours he appeared to be in very good condition. The sinus is almost closed now. The old chronic cases of empyema offer a good field for the use of differential pressure.

DR. A. J. OCHSNER, Chicago: At the Philadelphia meeting of this association I reported a series of cases such as Dr. Lilienthal described, in which we used the bismuth paste, following exactly the directions given by Beck. We have continued the use of the method; and while I have not the figures, much more than half of our patients have recovered permanently. The bismuth paste, however, must be administered in strict accordance with the directions given.

DR. JOSEPH RANSOHOFF, Cincinnati: During the recent epidemic I had about eighty cases of empyema. All the patients recovered. Abscess of the lung occurs in about 6 per cent. of the acute empyemas. Drains in both directions give a connection between the pleural cavity which is infected and the base of the lung. We did not discover this in our cases until we began the use of surgical solution of chlorinated soda, when some of the solution was coughed up with rather unpleasant complications. While empyema cases may be closed with fluid present and remain closed for two or three years, so long as there is any fluid in the pleural cavity there is the possibility of the relighting up of the infection. I agree fully with the statement that in some of these chronic cases the mere sterilization is not sufficient treatment. We must make a resection to free the lung and allow it to expand.

DR. JOSEPH A. BLAKE, New York: I agree with Dr. Ransohoff that the best treatment of chronic sinuses following empyema is their prevention. I believe also that in too many cases too much drainage is used at the primary operation, and that the drainage tubes and the treatment are responsible for the formation of sinuses. I regard it as absolutely wrong to use the Carrel-Dakin treatment in the early stages of the case. We would not, for instance, think of using Carrel-Dakin solution in the peritonitis or peritonitis, or in suppurative of the knee joint, with the tubes and constant irrigation. It was my unfortunate experience to see in France a very large number of patients in whom the Carrel tube had been left for a long time with a resultant sinus. The operation must be done with judgment; in some cases there is much material to be removed. The drainage tube should be left in for thirty-six hours, and care must be observed that sufficient drainage is secured.

Fractures of Lower Third of Femur

DR. JOSEPH VAN DE VELDE, La Pnne, Belgium: The compounding of these fractures during the war has considerably complicated the treatment. Open fractures by missiles we

divide into fractures: (1) with no comminution; (2) with slight comminution, and (3) with much comminution. For each of those types we used the following three methods of treatment: (1) wiring; (2) traction on the femoral condyles by ice tongs, Steinmann pins or Willems screws; (3) Depage's vertical suspension of lower fragment combined with horizontal traction on the leg. The first type of fracture is the ideal one for wiring. If, after debridement we plan to make a primary suture of the wound, we use Depage's wiring method because the metallic tube which sustains the wire comes out of the wound and affords good drainage. If we make a secondary suture, we use a Parham or bronze wire which we remove after a month before suturing the wound. In transverse fractures we use the ice tong or vertical suspension, and in a few cases we have used Lane's plates with good result. We do not recommend the use of screws in open contaminated fractures. In the second type of fracture primary suture is dangerous, and we therefore make a delayed primary of a secondary suture, and here the Steinmann pin offers the best method. It is placed just above the condyle. When this is not possible we pass it through the anterior part of the condyle under the control of a fluoroscopic screen, as recommended by Fessom. The pin should not be left in place more than six weeks. For the third type of fracture we use the vertical suspension, which is combined with a horizontal traction on the leg. The vertical suspension is accomplished by passing a bronze wire through all the tissues of the anterior part of the thigh with a Reverdin needle. A finger introduced into the wound catches the wire and fixes it securely around the end of the lower fragment. Traction is made by a weight hanging above the bed of the patient. Shortening of the femur is prevented by traction with a Chutro stirrup. Some of our fractured femurs were kept for three months with this apparatus without pain or complication. The method has been used with excellent result also in cases of badly united fracture of the lower third with fistula. Here we recommend the subperiosteal resection of the osteitic callus and a vertical suspension of the lower fragment. Those cases have done wonderfully well.

DISCUSSION

MR. W. HEY GROVES, London, England: In general terms I am quite in accord with Dr. Van de Velde's principles of treatment; but in certain details I think the matter is open for criticism. In fractures with no comminution I think the number requiring wiring is quite the exception, and that the operation should be limited to those cases in which the widely separated fragments show a real danger of the soft parts intervening. Even here, with the efficient extension apparatus which we have the cases are few. On the treatment of the second type of fractures I think we are in agreement. However, a pin right through the lower end of the thigh is bound to act as a seton, and in a small definite proportion of cases there will be sepsis, which in my own experience amounts to 3 per cent. This danger is entirely eliminated by the use of tibial transfixion. Dr. Van de Velde admitted that the ice tongs or Steinmann pins should not be left in place longer than six weeks, but my experience is that six weeks do not see us through. I venture to suggest, therefore, that in a great many cases it is of the greatest possible value to transfix the tibia and to put on a weight extension.

DR. A. PRUMST, Toronto, Canada: It is possible to close a gap in the skull by a graft of bone or cartilage. The operation is attended by little danger to life. The relief of symptoms directly dependent on the existence of the gap is, as a rule, immediate and complete, such as headache, dizziness, the fear of injury and sense of insecurity, mental depression and worry because of the possession of an ugly deformity. The value of the operation in jacksonian epilepsy is less evident except so far as one may succeed, by removing cortical irritation, in ameliorating the attacks. Symptoms dependent on organic cerebral lesions, such as defective vision, aphasia, loss of memory, deafness and loss of smell, are not improved by the operation. A fascial graft is of distinct value when a bone or cartilage graft is not borne. Finally, the conclusion is reached that when a cranial gap exists it should be closed. The symptoms caused by the existence of the gap will be relieved by a successful cranioplasty.

Scleroderma and Sclerodactyly.—This case presented by Atwater possesses many characteristics of the disease in its usual form. The associated sclerodactyly appears quite typical of those cases previously reported in which roentgenographic studies of the bones have been made. There is a characteristic atrophy, absorption and eventual disappearance of the terminal phalanges most commonly in the hands and sometimes in the feet.

Neurocirculatory Asthenia.—In Carrol's opinion some types of hyperthyroidism are analogous to neurocirculatory asthenia, and their pathogenesis is probably identical, the phenomena being attributable to a hyperexcitability of the opposing set of fibers of the autonomic nervous system. In both conditions the syndrome develops in individuals in whom there is a hyperirritability of one or other sets of fibers in the autonomic system. Hence, constitutional predisposition due to inherited sympathetic or vagotonic instability is a factor in the causation on a sound basis. Nervous and emotional strain is the immediate cause of susceptibility (acquired instability of the autonomic nervous system); infection plays a predominant rôle and the susceptibility in such cases may be accepted as indicating a chronicity of the infection with constant or frequent pourings into the blood of the infective agent. There is a certain rationale for believing that this instability in the autonomic nervous system lies in the element of anaphylaxis in disease in the predilection of anaphylatoxin for the parasympathetic system. There is some evidence that deficiencies of calcium in the diet may have played a part in the causation of some of the phenomena and that the higher plane of inorganic metabolism in the organism may have shared with epinephrin increase the responsibility in causation of the thyroid hyperplasia and hyperthyroidism among the soldiers.

Relation of Bacillus Influenza to Recent Epidemic.—The final conclusion reached by McDonnell is that the evidence at hand is not in favor of the influenza bacillus being considered the etiologic factor in the recent epidemic.

Deformity of Scapula Associated with Cervical Rib and Spina Bifida. G. H. Gopher, St. Louis.—p. 644.

Myxoma of Labium.—Fisher reports a case of pure myxoma of the right labium majus. The tumor never caused any pain and was insensitive to manipulation or pressure. It encroached on the pubic bone and infiltrated the surrounding soft tissues. The tumor weighed 7 pounds.

Fibroma of Abdominal Muscles.—This tumor was found growing in the fibers of the internal oblique and transversalis muscles. The external oblique was not adherent to it. The tumor seemed to be growing from the crest of the iliac bone.

Umbilical Teratoma.—The case cited by Brooks in which an isolated miniature intestinal apparatus was found at the umbilicus undoubtedly is an instance in which the omphalomesenteric duct failed to disappear entirely. The patient was a healthy child, 2 years of age, with no abnormalities, except those referable to the umbilicus. The umbilicus was replaced by an ulcer. The superior margin of the ulcer was overhanging. The lateral margins were sloping. Under the overhanging superior margin of the ulcer was a small sinus into which a probe could be passed for a distance of 3 cm. No chemical examination of the fluid was made. At operation on the peritoneal surface of the umbilical region was found a spherical tumor. There was no visible connection of this tumor with any other structure. On section the similarity of the tumor to tissue of the gastro-intestinal tract was revealed. Microscopic examination showed the spherical tumor to be composed of tissues corresponding to those forming normal intestine. Peritoneum, muscle, nerve cells, submucosa, lymphoid nodules and mucosa were all present in their usual relations. In the wall of the tumor adjacent to the peritoneum was a small island of normal pancreas. The gland was lobulated. The arrangement of the acini and ducts was the same as that of the normal pancreas.

Defecation, Urination and Menstruation by Rectum.—Keen cites the case of a woman, who for over thirty five years defecated and urinated and for eleven years menstruated by the rectum. The condition necessitating this use of the rectum was a case of extensive and incurable vesico-vaginal and recto-vaginal fistula caused by sloughing as a complication of typhoid. Ultimately Keen entirely closed the vaginal outlet.

Vaginal Hernia.—Sweetser cites a case of hernia protruding through the posterior vaginal wall. It was covered by peritoneum. The omentum was firmly attached to the uterus and broad ligaments. When the omentum was detached, the coils of bowel were separated and the uterus drawn forward, an opening was discovered in the center of the Douglas pouch, about 1 inch in diameter, through which the finger could be passed into the cyst below. There was no cyst wall above. The opening was closed by sutures, including the sacro-uterine ligaments. The abdomen was closed without drain. Returning to the vagina the sac was twisted into a cord, tied and cut off, and the levator muscles were sutured over the stump. The redundant vaginal wall was excised and the edges sutured.

End-to-End Intestinal Anastomosis.—This is a report of a clinical and experimental study of technic, indication and contraindications for end-to-end anastomosis of the small intestine and the colon. Soresi claims that, technically speaking, it is impossible with any method and the most perfect technic imaginable, to perform an end-to-end intestinal anastomosis, either of the small intestine or of the colon, with the positive certainty that leakage will not take place. The tissues found in the mesenteric space are infected and their blood supply is practically nil. In order to make it as safe as possible, whatever can lessen the resistance of the tissues concerned in the anastomosis must be avoided, such as unnecessary trauma, blood clots, great amount of suture material, unnecessary infection, knots, tight sutures; the blood supply must be left in the best condition obtainable with a safe and perfect hemostasis; all these desiderata are obtained with a technic originated and recommended by Soresi. He states further that the end-to-end method should always be resorted to in preference to any other method requiring more time when, and only when, time is the most important factor that will help to save a patient's life.

Construction of Liver Cell Protein by Carbohydrates.—Davis and his associates have been impressed with the great speed of repair of the normal liver following a type necrosis due to chloroform. A diet of bread and skim milk gives the optimum repair following a unit chloroform liver necrosis. A diet of cooked skeletal muscle is not as favorable for rapid liver repair as the rich carbohydrate diet. A diet of cooked liver or kidney is more favorable for rapid liver repair than a meat diet. Beef extract given alone does not favor liver repair, which indicates that meat extractives are not particularly concerned in the reaction of liver repair. Thyroid powder given in large doses with no food does not stimulate liver repair, but does accelerate tissue katabolism and increase nitrogen elimination. Brain feeding is favorable to liver regeneration and repair. Fat diets (vegetable oils, butter, lard, beef, fat, etc.) do not aid in liver regeneration.

Nonepidemic "Epidemic" Meningitis.—Eighteen cases of meningococcus meningitis in which the infection was apparently conveyed by a carrier are analyzed by Beech. In this series, eight of the patients received a serum, the titer of which was 1:200, or higher, for the organism recovered in each case. Each of these patients received an average of 278 c.c. of serum intraspinally and 191 c.c. intravenously. Five of the eight patients died, a mortality of 62.5 per cent. The mortality among the other ten cases was 70 per cent. Of these ten, the titer found in the serum, in one half of the cases was less than 1:200, and in the other half it was not determined. Five, or 27.6 per cent, of the patients showed purpura. Only one of these recovered.

Cerebral Complications of Mumps. Nine cases of cerebral complications occurring among 476 cases of mumps are reported by Haden, who believes that cerebral complications is probably mainly an encephalitis instead of a meningitis. Gram-positive cocci were demonstrated in the spinal fluid in one case. Animal inoculation and culture were negative. Lumbar puncture was a most effective therapeutic measure.

Oxygen Consumption of Human Erythrocytes. According to Harrop normal mature human erythrocytes have no oxygen

consumption measurable by present methods. Where it is measurably increased in the blood of individuals with anemia, the oxygen consumption has no relation to the severity of the anemia and no constant relation to histologic abnormalities in the erythrocytes other than increases in the number of reticulated cells. Blood which contains abnormal numbers of reticulated erythrocytes has an oxygen consumption proportional to the percentage of reticulated cells present. The data afford evidence that the two phenomena go hand in hand. Both are due to the presence of abnormal numbers of youthful cells, and both are probably rather accurate indicators of functional variations in the bone marrow and of the amount of blood regeneration.

- *Pathogenesis of Tabes Dorsalis. W. F. Schaller, San Francisco.—p. 749.
- Surgical Treatment of Injuries of Nervous System. C. A. Elsberg, New York.—p. 768.

Traumatic Abscess of Brain.—Experimental abscesses produced in the cortex of thirty-five cats by injury and infection of the brain resulted in a rapidly fatal process which simulated the traumatic injuries of the central nervous system in man. The affected part enlarged and brought about a marked dislocation and compression of the remainder of the nervous tissues. In 50 per cent. of the cases the infection reached the ventricular system within a few days, and from there usually spread into a basilar meningitis through the metapores of the fourth ventricle. The tendency of the infective process to invade the subarachnoid space from the point of injury was not marked, but in a third of the animals the infection entered the subdural space, forming there a subdural abscess. These lesions were very different from the more slowly growing abscesses extending from the air sinuses. The latter, occurring frequently in man, may be differentiated by the relatively slight swelling and dislocation, and by the development of a definite connective tissue capsule between the lesion and the sound parenchyma. The traumatic abscess in the experimental animal extended rapidly along the fiber tracts. No encapsulation could be demonstrated in any of these observations. Healing took place by ingrowth of connective tissue.

Carcinoma of Cerebral Meninges.—The reactive phenomena in the meninges to the presence of cancer cells, and the character of the meningeal involvement were studied by Hassin in one case which is reported in detail.

Eunuchoidism.—Four cases of congenital eunuchoidism, three of which, can easily be put into the class of status lymphaticus are reported by Climenko and Strauss. The first case gave clinical symptoms of apoplexy into the cord, a condition hitherto unreported, although apoplexies into the brain have been known to exist. The third case shows a sella condition that is also very rare and is contrary to the belief that in the eunuchoids the sella turcica is enlarged. It probably illustrates the fact that our judgment of the function of the pituitary must not be based on the size of the sella as evidenced through the roentgen-ray appearance. The fourth case is a mixed type of eunuchoidism with characteristic fat accumulations and strongly suggestive of status lymphaticus. In this case also the sella turcica was rather small. The second case is in a class by itself. The patient resembles the anthropoid much more than does the average human being. His skeletal frame looks as if it belonged to an intermediary stage between the human and the anthropoid. His intelligence is low.

Pathogenesis of Tabes Dorsalis.—Schaller is an adherent to the meningeal theory of tabes in the sense that the meningeal inflammation occasions in some manner the characteristic degenerations of the posterior roots and the posterior columns of the cord. Subacute syphilitic inflammatory

changes in the subarachnoid space (posterior leptomeningitis, meningeal and neural involvement of radicular nerve) are in etiologic relationship with the degeneration of the posterior roots. Likewise similar processes explain the cranial nerve involvement in tabes. The manner in which this subacute inflammatory meningitis produces root degeneration is as yet uncertain. It may act by direct extension of the meningeal lesions to the nerve roots causing a meningo-radculitis, or by pressure constiction from sclerosed meninges; by toxic products engendered by this inflammation or even by increase of fluid pressure, as is the case in posterior spinal root degeneration in brain tumor. These causes may act together or independently. This inflammation, which is constant in tabes to a greater or lesser degree, is evidenced by characteristic cerebrospinal fluid changes at one time or another in every case of tabes. Specific therapy in tabes should have for its object the reappearance of normal fluid reactions. Intraspinal therapy may be necessary to obtain this object. Conversely intraspinal treatment is contraindicated when the fluid shows no inflammatory reactions.

- *Action of Drugs on Output of Epinephrin from Suprarenals. I. Strychnin. G. N. Stewart and J. M. Rogoff.—p. 95.

Tropein.—According to Cushny, while tropein itself is devoid of the typical atropin action, many of its compounds, especially those containing the benzene nucleus, possess the characteristic action in some degree. This is greatly intensified by the presence of hydroxyl and asymmetric carbon in the side chain, and the highest degree of activity is reached only when tropein is combined with an acid of the benzene series, which contains a hydroxyl and an asymmetric carbon in the side chain, the whole molecule being levorotary.

Action of Strychnin on Output of Epinephrin from Suprarenals.—The authors found that strychnin causes a marked increase in the output of epinephrin. The increase is not transient but persists for a considerable time. No attempt was made to fix a minimum effective dose, but it was clearly shown that doses of strychnin well within the therapeutic range, and which caused little or no exaggeration of reflex excitability are capable of producing a considerable augmentation in the rate of output. Indications were obtained in some experiments that the stage of prolonged augmentation of the rate of output, which constitutes the principal action of the drug, may be preceded by a transient diminution. This phenomenon was best seen with the smaller doses and with subcutaneous administration of the drug.

Traumatic Rupture of Intestine.—A young man, 19 years of age, was struck by an automobile while riding on the tail board of another automobile. The accident occurred about two hours after the young man had eaten a full meal. There was complete division or rupture of the small intestine, 4 to 6 inches below where the duodenum crosses the vertebrae. This tear extended about 3½ inches into the mesentery. There was very little soiling of the peritoneum as the mucous membrane protruded through an opening and stopped the emptying of the intestinal contents into the cavity. The peritoneum was torn off the inner surface of the colon over a space of 2½ inches by 3½ inches. This was sutured in place. The intestine was closed by an end-to-side anastomosis. The patient recovered.

Deformities of Plantar and Anterior Arch.—Monkman says that the attitude of the medical profession should change from one of passive to active interest in advocating reform in the manufacture and sale of shoes. Freak styles in shoes should be subjected to a prohibitive tax to discourage their manufacture, preferably by federal enactment. The fitting of shoes should be supervised by a real orthopedist. Appliances for the feet should only be sold on the advice of the physician as is any other corrective measure.

Effects of Influenza on Pulmonary Tuberculosis.—Careful observation for four months, and reexamination of all patients affected with tuberculosis at the end of this period, showed that all the patients but two were none the worse for their experience, their general condition being as good as might have been expected normally. Tuberculous and nontuberculous subjects seemed to have been equally susceptible to influenza, the incidence in each case being 24 per cent. Early and advanced cases were equally affected. Pneumonic consolidations occurred as frequently in the nontuberculous as in the tuberculous.

Suprapubic Prostatectomy.—A new technic for a modified two and three stage operation, and absolute prevention of secondary hemorrhage is described by Sorensen. This modification aims to prevent the infection of the tissues surrounding the bladder. The first stage consists in suturing the unopened bladder to the skin under local anesthesia; the second stage is also the last if the surgeon deems it convenient to remove the prostate immediately. To prevent hemorrhage, Sorensen puts in the place from which the prostate, or part of it, was removed, a soft rubber bag, which is then filled with mercury. The pressure exercised by the heavy mercury is continuous, uniform, gentle and sufficient to compress the torn blood vessels.

Conductive Anesthesia by Intrasceral Extradural Injection of Procain.—The method described by Meaker is said to be a new one. When procain is injected extradurally into the bony canal of the sacrum, anesthesia of the third and lower sacral and coccygeal nerves is produced. The motor roots are not affected, and retention of urine after hemorrhoid operations done with sacral injections is neither more nor less common than when a general anesthetic is given. The regions supplied by the first and second posterior sacral nerves may undergo a paresthesia, but they are not anesthetized. The field of usefulness for sacral anesthesia is said to comprise operations for hemorrhoids, fistula and other conditions in and about the anus. In some cases the anesthesia is limited to a circle around the anus 3 or 4 inches in radius, while in others almost the whole of the buttocks may be analgesic. There is usually bilateral symmetry of effect. The lower rectum is anesthetized for at least 3 inches above the anus. The injection is to be made through the approximate center of the sacral hiatus.

Pandemic Influenza in Korea.—Schofield and Cynn believe that it is doubtful whether Pfeiffer's bacillus can be considered as the specific cause of the recent pandemic of influenza.

Injections of Typhoid Vaccine in Various Diseases.—Commercial typhoid vaccine, or typhoid paratyphoid vaccine, prepared for prophylactic inoculations, was used by Cadbury with good results in acute arthritis, rheumatic fever, chronic arthritis, syphilitic affections, various forms of neuralgic pain, psoriasis, lichen planus, itching of eczema and erythema induratum.

Tokelau (Tinea Imbricata) in Szechwan.—In the treatment of this disease Dubreuil used chrysophanic acid ointment, 10 per cent., mixed with petrolatum. At the end of two applications, given at an interval of about four days, the scales drop off, leaving only a fine red tracery showing where they had been. At the end of another week even these marks completely disappear and the skin resumes the normal healthy aspect. The achromia persists, however, for some time, and it is easy to distinguish the parts which were affected from the rest of the skin. If the treatment is stopped at this point the lesions reappear where they were before, except that on the back they are much more rare and scattered. If at this stage treatment is recommenced, the scars at once yield, but only to reappear directly treatment is abandoned. To avoid these recurrences, Dubreuil advises that the treatment should be conducted as follows: On the first day

the patient anoints with the chrysophanic acid ointment only one part of the body, as the legs, making use of a brush in order to work the application thoroughly into the skin, and taking great care not to allow any of the portion of the skin of that part, no matter how small, to remain untreated. On the two following days, if there has been no symptom of drug intoxication, the ointment is applied to the trunk of the body and to the neck. Finally, the face is treated, and care must be taken to wash the patient carefully and to remove the ointment by gentle rubbing with alcohol if there are signs of conjunctivitis. If this should happen the treatment can still be continued, but use must be made of chrysophanic acid, 10 gm.; guttapercha, 10 gm.; chloroform, 80 gm. With intermissions of one or two days, if necessary, the treatment is started again, and gone through twice completely in exactly the same manner. From then onward, that is to say, at the end of about ten or fifteen days, nothing further need be done, except to apply the ointment daily on the hands and feet, special care being taken concerning the portions of the skin immediately adjoining the nails. If no lesions appear during two weeks of careful scrutiny, all treatment may be stopped and the patient kept under careful surveillance for a period of from fifteen days to a month, after which he may be considered cured.

Charcot-Leyden Crystals in Diagnosis of Amebic Colitis.—Acton's examinations of cases have shown that there is no association between Charcot-Leyden crystals and intestinal entozoa. Charcot-Leyden crystals are more commonly present in the subacute and chronic types of amebiasis than in the acute type. They are rarely found in the nonamebic dysenteries. The association between Charcot-Leyden and *Endamoeba dysenterica* is very high. The presence of Charcot-Leyden crystals in the absence of amebas is indicative of amebic colitis. These crystals persist for some time after the amebas have disappeared as the result of emetin treatment.

- *Development of Artificial Mammal Carcinoma in Experimental Animals. Yataogawa and Ichikawa.

Development of Artificial Mammal Carcinoma in Experimental Animals.—The authors succeeded in producing an artificial epithelial carcinoma in the ear of the rabbit by the external application of tar. In the meantime the artificial tumor in the rabbit's ear had been found easily to ulcerate and by the heterogeneous infection of the various bacteria all the transplantation experiments proved negative. The authors therefore endeavored to develop the gland carcinoma artificially and for this purpose considered the mammary glands to be most convenient to treat. The first series of experimental animals were injected twice a month in the beginning of the experiment and later once a month with from 0.5 to 1.0 c.c. of the mixture of lanolin and watery extract of tar in proportion of 1:3 at the beginning and later 1:4. The injection was made at the mammary region and toward the mammary glands. The second series were

injected with the mixture of lanolin and the untreated tar in proportion of 4:1 into the rabbit that had been given the injection of the mixture of lanolin and the watery extract of tar (1:3) as the animals in the first series. The third series of animals were injected with the mixture of lanolin and tar (4:1) from the very beginning of the experiment, twice monthly for the beginning and once monthly afterward. The fourth series of animals was given 0.3 c.c. of tar into the excretory ducts by means of a slender needle inserted through the nipple. The animals belonging to the first and third series died within two days (the shortest) to 227 days (the longest); only one animal is still living. The animals of the second series lived from 70 to 227 days. In the fifth series, on the contrary, the animals lived for a considerably long period of time. One of the animals belonging to this series died on the four hundred and sixty-third day and proved the development of flat-epithelial carcinoma in the mammary glands. Although the experiment has not proceeded so far as to prove the involvements of other organs than the mammary gland, nor has the transplantation experiment been tried, but from the results so far attained, the authors conclude that the artificial development of mammary carcinoma is possible.

Detoxicated Vaccines.—Thomson is convinced that a prophylactic vaccine for bronchial and nasal catarrh is useless unless it is a mixed vaccine containing every species of germ giving rise to such attacks. He makes a compound detoxicated vaccine composed of a mixture of pneumococci, *M. catarrhalis*, *B. Friedländer*, *B. septicus*, streptococcus and *B. influenza* (Pfeiffer), containing 10,000 millions per cubic centimeter. The first dose is 1,500 millions; second dose, 3,000 millions; third dose, 3,000 millions. About 150 persons have been inoculated with two doses in this manner, and as no influenza or catarrhs have been recorded so far among them, except one very mild case, Thomson has considerable hope that this inoculation will prove of marked value in the prevention of these affections. Also during a catarrhal attack this compound inoculation has showed a marked power of bringing the infection to a rapid termination.

Case of Probable Rupture of Thoracic Duct.—Marten records the case of a man who fell from his motorcycle and landed heavily on the left shoulder. He was able to pick himself up and push his machine home, about 200 meters. He felt very much shaken and retired at once to bed. When dressing the next morning he noticed a large swelling in the left posterior triangle of the neck, somewhat tender to the touch, but soft and not blood stained. It was absolutely painless, almost doughy in consistence, irreducible, non-repitant, with no impulse on coughing. All the time the swelling was under observation it remained exactly the same. The diagnosis made by exclusion was injury to the thoracic duct, probably not the main duct, but one of the numerous

branches it frequently splits up into before it enters the subclaviojugular junction. Nothing was done.

Membranous Pericolicitis and Chronic Appendicitis.—Grégoire remarks that there are few symptoms so difficult to interpret as pain in the iliac fossa. The appendix may be removed without curing the pain, and he relates eight cases in which the appendix could be excised. Membranous pericolicitis can sometimes be incriminated. The vascular membrane that develops encloses the colon in a sac that is too short for it, and the colon has to bend. If a congenital origin for the membrane is accepted, then we can assume that the colon has been impeded in its growth, like the old custom of deforming the feet of Chinese women. The colon folded in on itself does not allow free passage of its contents. Between two angulations the loop becomes distended and painful, and stasis results. Relief can come only from releasing the colon from its hampering membrane, and fastening it so it cannot fall into the old bends again. In his cases he fastened the right portion of the transverse colon to the anterior abdominal wall. The subhepatic angle was opened wide by this procedure and the normal passage of feces insured. The cure has been complete and permanent in one for seven and one for four years among his eight patients treated by this means. The others are comparatively recent cases or have been lost to sight. The pains had persisted after removal of the appendix in four. In the others the abdominal attack had simulated acute appendicitis, but the membranous pericolicitis or Jackson's membrane had been recognized and corrected at the laparotomy. In these cases of constricting bands and membranes, the paroxysmal pain may suggest appendicitis, but the temperature and pulse keep normal during the attack and the abdominal wall does not stiffen. Some of the bismuth meal was retained in the cecum in one of his cases for sixty-four hours. The distension of the right colon is also characteristic, and its outline is smooth and roundish; the cecum end larger than the rest. The ascending colon and the transverse colon may be like the barrels of a gun, but the kink is movable. The dilatation of the origin of the large intestine is an argument against the assumption that mere movability of the cecum is responsible for the disturbances. The small intestine is naturally extremely movable but this does not induce dilatation and pain. Neither the movability nor the ptosis explains the lesion. The decisive factor is the obstacle against which the bowel beats and exhausts its muscular tonicity in vain. When it is released from this, the disturbances subside.

Loss of Nourishment in Dysentery. Loeper entitles his article "Les Spoliations Intestinales des Dysentériques" and expatiates on the anemia in these conditions. The losses of mineral substances and of iron in the multiple stools prevent normal regeneration of the blood. The red count is low and also the albumin content of the blood, while there is also a constant draining away of minerals. In treating dysentery, therefore, these facts must be borne in mind and the syst. is supplied with nitrogen, phosphorus and minerals. Meat, milk, and vegetables are needed especially in convalescence from dysentery. He does not venture always to give meat to convalescents. They may tolerate it scraped, raw, or very rare, but it may rouse the intestinal infection anew. Raw meat and meat juice are useful for their iron. But milk, he thinks, does not deserve the present ostracism in enteritis. If it induces fermentations and diarrhea, this is more annoying than harmful, and is by no means constant. The milk can be given in soups, gruels, with sodium citrate or lemon juice. It is generally borne well. Ascorbic milk is easier of digestion. Fresh cheese is nutritious. At one meal a purée of legumes might be given, but lentils and peas rather than beans. Macaroni and spaghetti also contain

albumin. To supply minerals directly is always a delicate matter. If the liver is working well, phosphorus in oil, 1:1,000, influences favorably the metabolism of minerals, especially of calcium. He advises giving it by intramuscular injection of 1 or 2 c.c. at most. This aids powerfully in the retention of calcium taken in the food.

- *Cure of Pulmonary Tuberculosis. L. Rénou.—p. 761.
- *Detection of Carbon Monoxid. A. Desgrez and A. Labat.—p. 764.

Teratoid Tumors of the Testicles.—Hartmann has compiled fifty cases and has examined personally twenty-seven. The ages of the subjects ranged from 16 to 43. In one case the tumor was in an undescended testicle. Trauma was recorded in some of the cases as having induced or accelerated the course of the tumor. Different embryomas correspond to different stages in the development of the ovum, hence he distinguishes between placentomas and choriomas, and devotes fourteen pages to this detailed study of thirteen of the former and fourteen of the chorioma type.

Caesarean Section for Uterine Tumors.—Tuffier says that this operation is preferable to hysterectomy for fibromas. He has performed it in 135 cases, leaving the woman with comparatively physiologic conditions in the genital sphere. During the same period of eighteen years he has a record of 131 hysterectomies for the same cause. The great objection to caesarean section is possible interference with pregnancy later, but nothing of the kind has occurred in his experience. One girl of 19 who had three fibromas removed by caesarean section has passed through three normal pregnancies since. At necropsy of one woman several years after the caesarean section there was not a trace of the operation to be found except a line on the body of the uterus. In three cases he enucleated large fibromas at the second or fourth month of the pregnancy and abortion followed in one of the cases. In the discussion that followed, Walther corroborated his statements and reported instances of normal pregnancy after enucleation of fibromas in young women. For older women he prefers hysterectomy, and he added that in some cases the development of new fibromas later finally compelled hysterectomy after all.

Operative Treatment of Scars from War Wounds.—Summarized in Paris Letter, p. 125.

Serotherapy of Typhoid Fever.—Rodet and Bonnamour report 127 cases of typhoid given injections of antiserum before the twelfth day. The total mortality was 11 per cent. but there was associated diphtheria or other disease in a number of the fourteen fatal cases. Eliminating these and the cases not seen till the twelfth day bring the death rate down to 2.9 per cent. Even in the fatal cases great benefit was apparent.

Test for Cure of Tuberculosis.—When everything seems to indicate a permanent cure of the pulmonary tuberculosis, Rénou settles the question by what he calls the test of *adaptation progressive à l'activité*. It takes three months; the subject works on alternate days for a few hours, morning or afternoon, with repose in the intervals. The number of hours of work is gradually increased and the days of repose gradually reduced. During the third month, the working hours should be complete. During these three months of gradual resumption of active life the subject should be supervised regularly in respect to weight, temperature, blood pressure and other signs. A slight loss of weight may be expected and also a slight lowering of the maximal blood pressure. But there should be no rise of temperature nor cough nor new expectoration nor the least rale on inspiration by auscultation of the suprascapular fossa. The fall is the best season for the test, the subject being thus in good trim for the critical spring months.

Test for Carbon Monoxid.—The test is made with paper impregnated with palladium chlorid.

Cancer of the Esophagus.—The woman of 52 had been having rebellious recurring eczema for thirty years when erythrodermia developed, with desquamation, the nails dropping off and the hair falling, with pruritus, emaciation and cachexia, and finally a spontaneous fracture of the tibia and a transient slight difficulty in swallowing. Roentgenoscopy then revealed a cancer in the esophagus, soon confirmed by necropsy, which disclosed multiple metastases in the brain, skeleton and liver. The erythrodermia was probably an early manifestation of the malignant disease.

Plastic Peritonitis.—The four children presented areas of hardness in the peritoneum, actual peritoneal plastrons, causing symptoms for a time but finally entirely resorbed at last. The course was subacute and slow, averaging about three months. The onset was sudden, as with acute peritonitis of appendicular, pneumococcus or gonococcus origin. This was followed by a slow remittent course; suppurative was feared at times and Morquio was on the point of operating more than once, when finally the whole subsided spontaneously. There was a variety of special manifestations according as the circumscribed lesion was located in the pelvis, epigastrium, kidney region or elsewhere. The tuberculin test was negative. In some of the children appendicitis seemed to be responsible and a small abscess in two cases was opened and drained, but an interval appendicectomy showed the appendix apparently sound. One of the children had vulvovaginitis and the peritoneal plastrons were evidently the work of the gonococcus. The children were from 3 to 13 years old.

Reflex Acute Edema of the Lung.—Tricoire remarks that while "pleural epilepsy" has been reported as a reflex accident in the course of thoracentesis, he thinks the case he describes is the first one to be recorded in which syncope and acute pulmonary edema developed from reflex action at the beginning of thoracentesis. The young man's chest had been traversed by a bullet four weeks before, but the wound had healed except for the left pleural effusion. Exploratory punctures had shown that it was sterile. The syncope and acute edema came on as only a few cubic centimeters of the effusion had been withdrawn. He recovered under spartein, venesection and wet cupping, after expectorating nearly a pint of foamy fluid. A similar reflex action was responsible for Flack's case of pulmonary edema from drinking iced water; in Jaccoud's case in typhoid from irritation of the abdominal sympathetic; in Vinay's from irritation of the sensory nerve terminals in the uterus, and in Pinaut's and Joulia's cases from puncture in ascites.

Azotemia and Urosecretory Coefficient in Acute Nephritis.—Ameuille and Sourdcl refer to the two, three or four months following acute and stormy nephritis. They had occasion to examine 101 men under these semilient conditions. They were impressed with the variability of the findings of the Ambard constant, and warn that several repetitions may be necessary to get an accurate estimate of the true condition.

- The Limits of Specialization. P. Mantoux.—p. 223.
- Proposed Reorganization of Medical Course. J. Bergonié.—p. 226.

Biologic Laws Governing Implants.—Roumeton relates experiences which demonstrate the general law that a healthy graft transplanted into pathologic tissue becomes pathologic

itself, while a pathologic graft transplanted into sound tissue may lose its pathologic tendency and grow normal in time. An interesting example of this is the Morax operation on the opaque cornea. With this, a disk is cut from the opaque cornea and another from the transparent periphery, and the disks are transposed. The transparent implant being permeable, like all autografts, becomes invaded by the abnormal elements surrounding it. The connective tissue persists unmodified, but the invading cells destroy its transparency and it gradually becomes opaque. On the other hand, the pathologic opaque graft, implanted in sound tissue, grows normal and in time becomes transparent. The two grafts thus progress in opposite directions, the direction determined by the normal or pathologic character of the bed. The cellular elements in each graft die off and are substituted by cells from the environment. If the environment is normal, the invading cells will aid in regeneration of normal tissue; otherwise not. The prospects therefore of plastic operations on the cornea are not very promising, but Bonneton's experiences confirm that if a small pathologic process can be cut out completely and then reimplanted in the old site, the environment being normal, it will be invaded by normal cells and lose its pathologic characteristics.

His theoretical premises have been effectually corroborated by his success in treating pterygium by this means. This pterygium process recurs again and again after its excision, so that with none of the operative procedures in vogue can a favorable result be guaranteed. But in the two cases treated on the basis of this biologic law, his success has surpassed his highest anticipations. He excised the pterygium far into sound tissue and transferred it to a glass slide. After staunching all bleeding he reimplanted the pterygium in its old bed, but turned it around, so that the head which had been adherent to the cornea faced the internal angle, and the base fitted against the corneal limbus. In twenty-four hours the pterygium had completely lost its morphologic characteristics. The vascular network was dislocated, destroyed, replaced. The following day the aspect of the graft was merely that of an irregular rectangle of a uniform cherry red, slightly edematous. The inflammatory phenomena soon subsided and from all sides, except the corneal limbus, delicate vessels could be seen making their way toward the center of the expterygium. In two or three weeks it was absolutely impossible to detect a trace of the former pterygium. The aspect is that merely of an ordinary autoplasmic graft of conjunctival tissue. He thinks these two experiences should interest surgeons generally as they confirm with precision the biologic laws deduced from his extensive experimental research. In the pterygium we can inspect with the naked eye the changes in implants which otherwise we have been able to trace only with the microscope.

*Influenza of the Thorax. R. Voisin and Benhamou—p. 421.

The Physiologic Jugular Venous Pulse. E. Stenon—p. 427.

*Vomiting of Infants. G. Schreier—p. 430.

Treatment of Influenza.—Voisin and Benhamou comment on the liver-kidney signs, the cardiovascular and the nervous signs which reveal the involvement of different organs. The physician has to be on the alert to detect insufficiency in the suprarenals and liver in their task of neutralizing toxins, insufficiency of the emunctories (liver, kidneys), and the violence of the general infection. The prognosis in malignant influenza depends on his prompt recognition of the signs of any of these and steering the patient past them. They describe in detail the treatment for each of these contingencies as they applied them during the pandemic, and credit their low death rate—3.5 per cent.—to their vigilant watch for these special signs outside of the respiratory apparatus.

Treatment of Vomiting in Infants.—Schreier advises in addition to regulation of the diet and application of hot compresses or ice to the stomach, lavage of the stomach two or three times a day if the vomit has a butyric odor or there are symptoms of intoxication. A teaspoonful of a solution of 2 gm. sodium citrate in 120 gm. distilled water may be

given just before or with the feeding. If the vomiting seems to be due to defective gastric secretion, hydrochloric acid or pepsin or both might be given, or pure gastric juice. With spasm of the stomach or pylorus, sedatives are indicated. Operative measures should be decided on promptly if medical measures fail.

*Radiology of Intestines. Raulot-Lapointe and F. Sorrel—p. 289.

*Rubeola. C. Lesieur and P. Jacquet—p. 292.

Exploration of the Large Intestine.—Lapointe and Sorrel state that they have never had the slightest mishap with bismuth carbonate which they have used for the contrast meal more than 2400 times. They expatiate on the special advantages of orthodiagrams, and of the practice of giving the bismuth in an enema for radioscopy, to supplement the findings of the contrast meal.

Blood and Gland Reactions in Rubeola.—Lesieur and Jacquet call attention to the enlargement of the suprathoracic gland which was a constant finding in all their cases of rubeola. It is seldom palpable in health but it was found plainly enlarged on palpation on one or both sides in all their cases of rubeola. The blood findings also seemed to be characteristic, a mononuclear leukocytosis, affecting mostly the medium forms, with a slight mast-cell leukocytosis with beginning convalescence. In measles, there is only the ordinary polynuclear leukocytosis; in scarlet fever, polymucositis is pronounced.

Latent Gastric Cancer with Metastases in the Bones. Rodier—p. 196.

Early Diagnosis of Pulmonary Tuberculosis.—Philibert warns that percussion and auscultation should be done with the mouth open and repeated with the mouth closed, to eliminate modifications for which the narrowness of one or both of the nasal passages may be responsible. There may be no fever with incipient tuberculosis, but the temperature responds with an excessive reaction to slight harmless causes, and this thermic instability may turn the scale. It can be tested with an injection of saline or by the thermic effect of an hour's walk. He keeps the soldier a week in bed and then examines him again after he has been up a week. To obtain sputum, if there is no expectoration, he gives a potion consisting of 0.5 gm. white oxid of antimony in 120 gm. of a mucilaginous vehicle. This stimulates bronchial secretion. If the findings are negative even with homogenized sputum, the test can be repeated later at weekly intervals two or more times. If the temperature runs up after a moderate walk of an hour, this signifies that whatever the cause, repose is indicated, especially if other signs point to tuberculosis.

The Reaction to Epinephrin in Hyperthyroidism.—Bernard reviews some recent works on the influence of epinephrin when the thyroid is functioning to excess. With hyperthyroidism there is evidently some special susceptibility to epinephrin on the part of the sympathetic vasomotor nerve terminals. An injection of 0.5 mg. of epinephrin will induce

tachycardia, and send up the blood pressure, and it may not return to normal for an hour and a half. This test reaction is important in dubious cases suggesting exophthalmic goiter but without the cardinal signs of it. An operation on the thyroid in such cases often reveals the thyroid studded with small adenomas, too small to be palpated. The subsidence of all the symptoms afterward confirms the assumption of the causal hyperthyroidism. This is particularly important in the group of cases in which the excessive functioning of the thyroid is responsible for conditions labeled psychoneuroses, psychasthenia and neurasthenia, without any appreciable ocular, vasomotor or cardiac symptoms. The slightly positive reaction to the epinephrin test encourages an operation on the thyroid, and this reveals numerous small adenomas in the gland.

Outcome of Surgical Tuberculosis. De Quervain and Hunziker.—p. 701.
Children's Psoriasis for Contagious Disease. F. Forst.—p. 777.

Outcome with Surgical Tuberculosis. De Quervain and Hunziker report on the present condition of 537 patients given operative treatment at Basel in 1913. The data presented show that tuberculous processes in fingers, toes, wrists, glands, tendons, soft parts and skin can be successfully treated almost anywhere. With tuberculous lesions in ribs, sternum, clavicle, scapula, radius or ulna, urogenital organs, intestines or peritoneum one is justified in applying treatment in the mountains or the lowlands as most convenient. But treatment in a mountain climate is extremely desirable with tuberculous lesions in the spine, pelvis, humerus, shoulder, femur, tibia or fibula, and in the hip, knee and ankle joints. The advantages of a mountain climate in this group are evident in his figures, and he expatiates on the necessity for a mountain sanatorium for this group as an annex to other hospitals. For the whole of Switzerland, probably one fifth of the average 15,000 cases of surgical tuberculosis require altitude treatment in addition to the other measures. The aim should be therefore to provide mountain sanatorium accommodations for these 3,000 that require it, with a system of interchanges between sanatoriums and hospitals to give this special group the advantages of altitude. Even those patients already living in the mountains need the care and training of a sanatorium. The course of treatment with surgical tuberculosis usually takes one or more years while the course with pulmonary tuberculosis is generally restricted to a few months. As children form the large contingent of surgical tuberculosis cases, the loss of time does not matter so much. The system of sanatoriums should be supplemented with institutions where the convalescent and recovered should be gradually accustomed to resume work and train for future activity under medical supervision. There should be a kind of employment bureau in connection, designed for these more or less handicapped persons.

Contagious Disease Hospital for Children. Feer relates that in a total of 4,000 cases of various infections, from measles and scarlet fever to poliomyelitis, in the last three years at the children's clinic at Zurich he only had two cases of dense infection develop, and in both of these instances an available broken link in the chain was detected. This paved the way for the glass cubicle plan and even the larger rooms can be partitioned off with glass walls. The hospital has thirty beds and they have been constantly occupied. Different infectious diseases succeeding each other in the same cubicle, with only the two instances of house infection

mentioned above. No one enters the cubicle except the one or two nurses, and they enter it as seldom as possible and then attend to everything at once, take the temperature, etc. The medicines and packs are ordered without too brief intervals. He adds that it is not a mere coincidence that the two cases of house infection were with measles and varicella. These are spread so easily that he insists on the window being shut from without before the cubicle is entered when it contains a patient with either of these diseases. Among other practical points noted is the warning that simple measles and influenza cases develop pneumonia as soon as a case of pneumonia is placed near them. Feer extols this cubicle type of hospital as the ideal for small towns. It is much better supervised and can be run with less expense than hospitals with special departments devoted exclusively to scarlet fever or diphtheria.

Gazzetta degli Ospedali e delle Cliniche, Rome

May 1, 1919, 40, No. 35

Post-Typhoid Complications in Bones. U. Tassone.—p. 329.

Post-Typhoid Complications in the Bones.—Tassone reports the case of a young man who developed multiple abscesses in different bones, with a tendency to hyperplasia at different points that compelled surgical intervention. Typhoid bacilli were cultivated constantly from the pus. The bone complications may not develop until after quite an interval. Adolescents form the majority of those affected, and the tibia, scapula and metatarsus are the bones usually involved. Trauma may aid in starting the process. It may manifest itself only by rheumatoid pains with final spontaneous resolution. Or there may be acute or chronic osteoperiostitis with or without much destruction of tissue. These complications usually develop during convalescence, accompanied by a little fever, worse at night as a rule. There may be an interval of several months before the chronic form develops, and the course may suggest a cold abscess lingering for months or years. The typhoid bacilli cultivated from these indolent processes may display great virulence, showing that the slow course is determined by the resisting power of the tissues. The chronic nonsuppurating type may entail production of exostoses and deformity requiring surgical measures; the pains with this are of the same type as in the chronic suppurating form. The deformity may affect both legs, with actually crippling contracture and atrophy of the muscles as in Chantemesse's case, but this is extremely rare. He reports a case of this kind in a robust young farmer. During convalescence from the typhoid he complained of pains throughout his body but they finally settled in one foot, but after incision of the abscess here, others developed at various points. Hyperplastic processes rapidly developed crippling him and finally requiring operative correction for knee and ankle, with resection of bone and section of the Achilles tendon. The typhoid bacillus seemed to be solely responsible for the various lesions. The operation was done nearly three months after the onset of the typhoid fever and three more months passed before the young man was discharged completely cured, his joints functioning normally.

Pediatria, Naples

June, 1919, 27, No. 6

Initial Phase of Scurvy in Infants. O. Cozzolino.—p. 331. Contin.
The Wassermann Reaction with Human Milk. C. L. Rusca.—p. 343.
Hemorrhagic Menstrual Complications with Whooping Cough. A. F. Gualdi.—p. 351.

The Wassermann Reaction with Human Milk.—Rusca examined breast milk from forty women, including fifteen free from syphilis and sixteen with certain syphilis. The response was constantly negative in milk from normal women at the second to the ninth month of pregnancy but there was

a weak reaction in the colostrum milk. The reaction was always pronounced in milk from the syphilitic women but, under treatment, the reaction disappeared from the milk parallel to its disappearance from the blood. By testing the milk we can thus gain an insight into the woman's condition without her knowledge.

Meningeal Complications of Whooping Cough.—Canelli found at necropsy of two infants, 6 to 23 months old, who had died during whooping cough, pathologic changes in meninges and brain. These intracranial lesions seemed to be direct complications of the pertussis. Both children had been born spontaneously and there had been no signs of a nervous affection until the brain and meningeal symptoms developed after whooping cough had been installed for a few weeks. There was nothing else found or learned to explain the lesions. Both infants died in coma. No histologic lesions were found in the intracranial vessels. It is possible that the minute hemorrhagic foci in brain and meninges may have been due to the action of carbon dioxide from the asphyxia during a coughing paroxysm or to the increased blood pressure during a spasm, but the vessels could not have yielded unless they had been already weakened by the toxic infectious action of the pertussis.

Policlinico, Rome

The Pandemic of Influenza. A. Morassini, p. 705.

Asthma. G. Sabatini, p. 709. *Cont'd* No. 24, p. 675.

Case of Elephantiasis of the Vulva. J. Aboulaque, p. 722.

Asthma.—Sabatini remarks that few ailments have had such an abundant flora of remedies of all kinds as asthma, empiric and scientific. The treatment has to be twofold, to arrest the attack and abolish the cause. We can act to arrest the spasm of the constricting muscles or to stimulate the dilating muscles. Epinephrin and pituitary extract have proved their usefulness in arresting an attack. His experience and that of others seems to indicate that even prolonged administration of these two is harmless. He knows of a man of 65 who has been taking almost daily injections for six years of a preparation containing both these, and he has never shown the slightest sign of general disturbance from it. The theoretical fear that it might send the blood pressure up has not been confirmed by experience; the patient referred to has still a pressure rather below what might be expected at his age. Intrabronchial sprays of epinephrin are uncertain, and Sabatini regards them as unequalled for "as the subcutaneous injection is so magnificently certain," although the mechanism of its action is still unknown. Treatment of asthma on the basis of its being a manifestation of anaphylaxis has been much simplified by the use of peptone. This seems to desensitize in cases of asthma, whatever the antigen responsible for the sensitization. Time and experience will show what to expect from peptone treatment. It is too early yet to determine definitely its efficacy in such an obscure, capricious and rebellious malady as asthma.

May, 1919, 26, Medical Section No. 5

*Amebic Abscess in Liver. T. Pontano, p. 169.

*Relative Seroprophylaxis in Influenza. G. Tizzoni and G. Vernoni, p. 187.

*Pleuro-Typhoid. F. Mondolfo, p. 193.

Malaria in Italian Soldiers. C. Pezzi, p. 199. *Cont'd.*

Amebic Liver Disease.—Pontano remarks that the absence of amebias from the stools does not exclude the amebic origin of an abscess in the liver. The abscess is not always single, and there may be no history of dysentery in the antecedents. Of great differential importance, however, are the microscopic findings in the puncture fluid from the abscess. It consists mostly of cellular detritus, hematoidin crystals and a few scattered reds, with droplets of fat and a few rare whites scarcely recognized and not taking anilin stains, while the fluid is usually bacteriologically sterile. He cites various authorities who emphasize the difference between this colliquative necrotic process and true inflammatory supuration. In the first of Pontano's two cases the abscess developed in the liver six years after the amebic dysentery, but in the

second case there never had been any appreciable symptom of dysentery at any time. No amebias had been found in the stools or by exploratory puncture, and the abscesses were sterile except for the colon bacillus in one case. The abscess contents were the characteristic albuminous fluid with detritus instead of pus, and the prompt cure in both cases under emetin confirmed the diagnosis. The abscesses retrogressed and were absorbed under vigorous subcutaneous emetin treatment.

Seroprophylaxis of Influenza.—Tizzoni and Vernoni found the richest bacterial flora in influenza in the lungs and pleural effusion, streptococci and staphylococci predominating. The former seemed to be of a special type in the complicated cases, intermediate between the pneumococcus and the streptococcus. It induced invariably in rabbits and mice fatal pleural, pulmonary and peritoneal processes, and they regard it as unmistakably responsible for the complications of influenza. They injected two horses with two strains of this bacterium, and then injected animals by the vein with the serum from these horses, twenty-four hours before injecting them in the pleura with cultures of the bacterium in a dose sufficient to kill the controls. The controls all died from the fourth to the ninth day with purulent pleuro-pericarditis, but the serum-treated animals all survived. The serum, however, proved effectual only for the same strain that had been used in procuring the anti-serum. They regard this experimental work as promising an effectual treatment to ward off the complications of influenza, until we discover means to ward off the disease itself.

Typhoid Pleuritis.—The robust man recovered after nearly an eight weeks' course. The symptoms from the pleura were the first to appear, and with a stormy onset, not explained until the twelfth day disclosed typhoid bacilli both in the pleural effusion and in the blood. Tests the sixth day had been negative. The ordinary symptoms of typhoid, enlargement of the spleen, epistaxis and watery stools did not appear till the second or third week. Mondolfo compares this case with similar ones on record. The earlier the involvement of the pleura, the milder the case seems to be, he states. Late typhoid pleuritis is liable to become purulent.

*Surgical Aid to Remineralization in Tuberculous Hip Joint Disease. D. Maragliano, p. 394.

*Erythrodermia with Chronic Articular Rheumatism. P. J. Arollano, p. 397.

*Quinin, Malaria and Influenza. T. Silvestri, p. 402.

*Diagnosis of Esophageal Tumors. G. Minniti, p. 406.

*Set of Symptoms from Injury of Last Four Cranial Nerves. F. Aiccoli, p. 404.

Surgical Remineralization in Tuberculous Hip Joint Disease.—Maragliano here shows the ultimate outcome in the first two cases of tuberculous coxitis in which he sought to combat the demineralization by introducing a bone and periosteum implant. The patients were a boy of 5 and a girl of 8, and radiocopy showed pronounced demineralization in the healed process. He then drove a bar of bone tissue, taken from the tibia, through the neck, head and cotyle, hoping to supply this at the spot the minerals needed for the regeneration of the bone. He here gives the radiograms of the cases taken four years later. They testify to the favorable and definite results obtained. Everything seems to indicate that the bone implant materially facilitated and hastened complete repair. The stiff joint in the boy has gradually regained its function. The coxitis in the girl has been so extensive and destructive that the regeneration in eight months was a great surprise. The implant of bone and periosteum was completely absorbed in time in both cases. His previous article on the subject was summarized in this column recently, June 7, 1919, p. 1709.

Chronic Rheumatism and Dermatoses.—Arollano concludes from the five cases he has encountered that uric acid occurs in the blood more often than is generally recognized. It can be readily detected by Garrod's throat test. The uric acid may be responsible for certain unusual skin affections as well as for chronic articular rheumatism. In the past,

genesis of chronic articular rheumatism a special soil, inherited or acquired, can always be assumed.

Quinin, Malaria and Influenza.—Silvestri asserts that the malaria, rather than the quinin, was responsible for the way in which the malarial inmates of hospitals escaped influenza during the pandemic. Not only malaria, but any infectious disease seems to protect against influenza while it lasts. This immunity ceases however, after recovery, and during long latent periods in malaria. He emphasizes that these facts confirm anew the slight resisting power of the influenza virus in respect to other germs. Secondary infections over and over and crowd out the influenza virus, the patient rapidly becoming harmless, so far as infecting others is concerned. Search for the influenza virus, therefore, is bound to fail, if secondary infections are already installed. Only in the first three or four days at most are we liable to encounter it. The systematic use of quinin in prophylaxis of influenza does not seem effectual in warding off the disease, at least in the doses usually given, up to 1 or 1.2 gm. per day. But the quinin given in this way seemed to have a pronounced attenuating influence on the course of the influenza when it developed. This was also observed with quinin given systematically in scarlet fever and measles.

*Recent Research on Hookworm in Indonesia. S. T. Darling. p. 25.
Six Operative Cases of Foreign Bodies in Alimentary Canal. M. Gatti. —p. 39.

Hookworm in the Malay States and Netherlands Indies.—Darling's research was conducted under the auspices of the Rockefeller Foundation. He relates that malaria is so frequent in Indonesia and hookworm so prevalent that it is difficult to tell to which to attribute the anemia. He tabulates the figures for different localities and the treatment found most effectual. It was found that the initial purge could be omitted without detriment, which rendered it possible to treat larger numbers in less time. But it is indispensable to refrain from eating, the morning of the day the chenopodium is taken, and the afternoon and evening meals must be light, leaving little residue. The stomach and small intestine should be empty, as otherwise the drug is absorbed and its action impeded by particles of food.

*Early Diagnosis of Uterine Cancer. Vidal Azu. p. 97.
Venerection in Eclampsia. H. Bonquet. p. 106.
Infernal Pleuresy. H. Bonquet. —p. 106.

Early Diagnosis of Uterine Cancer.—Azu joins in the universal lament that nearly 90 per cent. of the cases of uterine cancer are beyond medical and surgical aid when first seen by the physician. The family physician and midwives are not enough on the alert to detect cancer, and the women themselves pay no heed to their symptoms. It seems to be impossible to convince women that repeated losses of blood are not a normal feature of the menopause. Even when the family physician is consulted, too often he reassures the woman that her hemorrhages have no significance and will soon right themselves, or he prescribes merely ergot or hamamelis. If the woman is young, the opinion of the family physician is usually even greater. Few insist on palpation of the vagina, and precious time is wasted while the woman's doom is being sealed. Even when the physician palpates the vagina, he is apt to discard all suspicion of cancer if the cervix feels normal, while the cancer in the fundus proceeds in its course. Thus tranquilized by their family physicians, the women pass to their doom until pains and acid discharges drive them to the specialist. It is remarkable, Azu declares, how placidly women regard even extensive genital hemorrhages. A loss of even 50 gm. of blood from mouth or nose would send them in alarm to the physician, but they seem to be calmly indifferent to losses of blood by the genitals of a pint or even a quart of blood.

They even seem to be proud of these genital hemorrhages, as an expression of their sex. Only when the genital hemorrhages are brought on by a known trauma are the women disquieted by them. Cancer should be regarded as practically certain when there are repeated spontaneous or traumatic losses of blood, no matter how minute, or oozing of "meat washing water," at intervals of ten or twelve days or less, and the cervix does not feel quite normal. Azu now has in his charge two women of 26 and 23 presenting these unmistakable findings. Even when the cervix is normal, there may be a cancer in the fundus. Any hard, friable excrecence that bleeds readily and can be fragmented with the finger nail is cancerous, as well as actual ulceration in the cervix. Where there is the slightest doubt, a scrap of the cervix or uterine mucosa should be sent to some laboratory for examination.

*The Island of Langerhans and Its Endocrine Function. P. J. Garcia. —p. 7.

*Clinical and Surgical Comparison of Pubiectomy and Symphysiotomy. D. Iraeta. —p. 27.

The Island of Langerhans.—Garcia analyzes what has been published on the possible endocrine function of the pancreas, and warns that the idea that the islands of Langerhans are closed follicles must be abandoned once for all. They are formed of epithelial cells, and they undoubtedly pour an internal secretion directly into the blood vessels, but at the same time they discharge an external secretion. This dual secretion is bipolar, possibly alternate, but not simultaneous, like the secretion in the liver. The islands of Langerhans and the acini seem to be reversible after a certain time. Regulation of sugar metabolism also seems to be under the control of the secretion of the islands of Langerhans.

Pubiectomy versus Symphysiotomy.—Iraeta devotes over a hundred pages to this study of the comparative advantages of these methods. There are fifty-seven illustrations in the text. His final decision is in favor of symphysiotomy for various reasons, especially the ease, simplicity and security of the technic under local anesthesia.

*Insufficiency of the Pancreas in Children. C. S. de los Terreros. —p. 353.

*Chronic Vesiculitis. A. Pulido Martín. —p. 356.
Influenza. C. M. González. —p. 360.

Insufficiency of the Pancreas in Children.—Terreros explains that the pancreas function does not become installed until about the fifth month of life, and even then may not be complete for a time. This is a factor in the disturbances in children under 2 fed too exclusively on any starch, or given meat prematurely. This throws so much work on the pancreas that it becomes exhausted. Even in older children this insufficiency of the pancreas occurs more often than generally recognized. A test meal with a given amount of fat, butter, for example, will show a much larger proportion of fat in the stools than would be the case in a normal child. More than two thirds is passed unutilized. The stools are pasty and bulky, with visible fat, and the urine is ammoniacal. In young children a change of diet answers the purpose. In older children the pancreas may be too pathologic for proper function and organotherapy may be advisable. He warns that he has often found commercial preparations of the pancreas unreliable, and has been forced to use the fresh gland (pieces weighing 0.5 gm. enclosed in capsules that are not dissolved by the gastric juice). The blood in his cases showed slight anemia, leukopeny and lymphocytosis. This seems to be the principal cause of the low blood pressure, the emaciation and the infantilism. He has never succeeded in palpating the pancreas in children.

Treatment of Chronic Inflammation in the Seminal Vesicles.—Pulido Martin emphasizes the importance of lesions in the seminal vesicles as responsible for certain persisting periurethral processes and chronic gonorrheal pseudorheumatism. In about 50 per cent. of the cases the vesicles give no sign of trouble, but in the others the symptoms may be intolerable. They are often mistakenly credited to the prostate and the prostate is maltreated in consequence. As a rule, however, the physician has to locate the source of the disturbances by the history of the case, by palpation, through the rectum, of the vesicles with fingers and instrument, by microscopic examination of the fluid, and by transillumination. With chronic pseudorheumatism and recurring epididymitis, especially the alternating form, the seminal vesicles will be found diseased as also with tenacious urethritis. His experience has been very favorable with injection of a germicide into the vas deferens, to reach the vesicles by this indirect route. The amount injected is too small to induce muscular contraction in the vesicles, so it is not expelled by them if they have previously been emptied by massage. Whatever the theoretical objections to this, the practical results have been most gratifying. He does not suture the minute opening made in the vas deferens but closes it with collodion before suturing the skin over it; this has always answered the purpose. He has never had pain or inflammatory reaction in or around the vas or in the epididymis. He gives the details of seven cases cured by this means of chronic disturbances, reaffirming in conclusion that in half the cases the seminal vesicles themselves are silent although responsible for the chronic disturbances.

*Action of Peptone on the Circulation. S. Kondo.—p. 1.

*Action of Veratrin on the Vessels. S. Kondo.—p. 19.

*Nature of Trachoma. K. Hiwatari.—p. 31.

*Formation by Bacteria of β -beta Imitadizyl-Lactic Acid from Ethylol

K. Hirai.—p. 49.

*Origin of Blood Cells. K. Kiyono and T. Nakanoin.—p. 55.

*Elimination of Cleavage Products of Albumin. N. Suzuki.—p. 139.

Action of Peptone on the Circulation of Blood.—Kondo's experimental research has confirmed that peptone injected intravenously reduces the blood pressure and has a constricting action on the vessels in legs and ears, while it dilates the splanchnic vessels. The constricting action on the vessels in the rabbit ear is followed by a relaxation which occurs earlier the higher the concentration. If constriction has already occurred under the influence of epinephrin, the peptone does not constrict the vessel further but the contraction of the vessel subsides rather earlier than under the influence of Ringer's solution.

Action of Veratrin on the Vessels.—Kondo reports experiences which seem to demonstrate that veratrin, like epinephrin, acts on the nervous elements in the vessel wall. Its powerful vasoconstricting action relaxes somewhat when the vessels are continuously irrigated with it. The constricting action does not manifest itself if the vessels have been previously irrigated with 0.01 per cent. quinin or 0.05 per cent. atropin. Epinephrin behaves in the same way to quinin and atropin. On the other hand, tests with a barium salt showed that its vasoconstrictor action was not modified by the quinin and atropin. He accepts this as evidence that barium acts on the contractile rather than on the nerve elements in the vessels.

Nature of Trachoma. Hiwatari discusses both trachoma and the normal histology of the conjunctiva, with a large colored plate.

Origin of Blood Cells.—Kiyono and Nakanoin trace the pedigree and the development of the cells in minute detail through the three stages of blood production, embryonal, etc. They show fifty-seven stained specimens in four large colored plates, with nearly six pages of bibliography. They assert that what they call the "histiocytes" diverge early from the lymphoid stem. They review the morphology of the histiocyte cells in mammals and cold-blooded animals, their functions, their place in ontogenesis and phylogenesis, and report research with vital staining in invertebrates.

Elimination of Albumin Cleavage Products.—This first communication on Suzuki's research in this line, describes the occurrence of phenaceturic acid in normal goat urine, with special regard to the relations between the food and the elimination of the acid.

*Automatism and Coordination of the Heart. S. Nukada.—p. 1

Automatism and Coordination of the Heart.—Nukada's monograph fills this entire number, 164 pages, and is accompanied by twenty-one plates, many of them colored. The research was done mainly on the heart of *Limulus longispina*, a species of king-crabs, but the findings were compared with those in vertebrates, reptiles, etc. The electrocardiograms of the limulus heart are very much like those of the mammalian heart. In both, he concludes, the nerve tissue seems to be responsible for the heart beat; the muscles take no part in the formation or transmission of the impulse or the coordination of the heart. The sinus node and bundle are merely a prolongation of the auricle which accompanies the nerve tissue and possibly supports and protects it.

*Scrofulous Ophthalmia. L. K. Wolff.—p. 1168

*Latent Sinusitis with Reflex Neuritis. J. C. Henkes.—p. 1177

*Visual Disturbance with Wounds of Back of Head. G. ten Doeschate.—p. 1183.

Nature and Treatment of "Scrofulous" Ophthalmia. Wolff apologizes for retaining this term, but says it conveniently classifies the cases in which at some time there has been a tuberculous inflammation in the eye, leaving it hypersensitive to the tuberculous toxin. Certain lymph glands in the vicinity may also have been the seat of a tuberculous process which may or may not have subsided into a latent stage. In any event, the tuberculous toxin occasionally gets mobilized, and when it reaches the hypersensitive eye it induces phlyctenosis. The latter do not develop in animals, and tuberculous processes in the neck glands seldom occur in animals except possibly in the hog. Wolff urges examination of the eyes when tuberculous processes are found in the cervical glands in hogs. It is possible that obstinate eczema may likewise be a manifestation of local toxic action on a healed tuberculous lesion which has left the area hypersensitive. Other germs play a secondary but important rôle. Treatment may aim to abolish the tuberculous foci generating the toxins which act on the eye, or it may aim to reduce the

sensitiveness of the eye. A course of tuberculin would aid in the latter, but roentgen treatment of the tuberculous glands has proved the simplest and easiest method to eradicate the toxin-generating foci. No operative measures were attempted except to aspirate when necessary. At most 4 H. U. units were given at a time, with an aluminum filter 5 mm. thick. Roentgen exposures have no influence on the phlyctenular inflammation or corneal ulcer itself, but exposures of the tuberculous glands dry up the stream of toxins at its source. As adjuvant he has found silver fluorescein useful, especially in a 5 per cent. saline in white petrolatum, applying a little every hour in the conjunctival sac. The same principles were applied in treatment of benign tumors of the eye, and the glandular lesions in the neck retrogressed without recurrence in three of four cases, but the eye lesion was not influenced, in contrast to what is observed with the phlyctenular ophthalmia. The latter disappears as the glandular lesions retrogress, as he shows in a table of fourteen cases. After removal of a sarcoma of the conjunctiva in another case, the eye was subjected to roentgen exposures and no harm seemed to have been done, no microscopic changes from them were evident when the eye was enucleated over two years later on account of recurrence of the sarcoma. Encouraged by this, he applied the roentgen rays directly to the eye and with brilliant success in his first two cases. One was a girl of 18 with iridocyclitis and numerous nodules in the iris; the other patient had keratoscleritis with an ulcerating nodule in the cornea. The lesions were entirely cured in a few days, but there was recurrence in the second case. In three other cases of scleritis great benefit was derived, but not so promptly. The lymph glands had better be exposed at the same time, he says.

Latent Sinusitis with Reflex Neuroses.—Henkes describes a form of latent sinusitis affecting the ethmoidal sinus alone, a hyperplastic ethmoiditis which may generate certain reflex neuroses. The only objective sign of it may be that the middle turbinate bone may be somewhat enlarged and the mucosa a little swollen. This periodical hyperemia and swelling exerts a greater irritation on the nerves and tissues than a polyp or other benign process in the nose. A simple operation on the sinus frees the patient at once from his "neurasthenia," "Ménière's disease," "hay-fever," "nervous rhinorrhea" or other complaint of the kind. In one case of Ménière's disease he removed the left middle turbinate as it seemed to be exceptionally large although all around seemed normal. This left exposed a large cell filled with granulation tissue and cells of the ethmoidal sinus were found filled with the same. After these pathologic cells had been removed, the Ménière's disease of many years' standing was cured completely at once. The irritation responsible for it must have proceeded from the otherwise entirely latent pathologic process in this sinus. He introduces far back in each side of the nose an electric light from a cystoscope and the light is turned on in both together. Asymmetrical findings on a line just below the eyebrows call for further investigation. In one case the scanty symptoms pointed to the frontal sinus.

Hospitalstidende, Copenhagen

Mo. 7, 1919, 62, No. 19

*Roentgen Treatment of Hypertrophied Breasts. C. Røysing, p. 577.
*Vaccination against Typhus. O. Thomsen, p. 588.

Roentgen Treatment of Hypertrophied Breasts.—Røysing's patient was an unmarried woman of 27, and her breasts had begun to enlarge about eighteen months before. They grew painful and tender with no relief from supports. The skin was normal. A few glands in the axillae were enlarged and tender. Menstruation was normal throughout. An incision in the upper quadrant of one breast showed hard fibrous tissue. Roentgen exposures were then given, twice 6 H. U. units (3 mm. aluminum), to each breast, and three months later 20 H. U. (5 mm. aluminum). The right breast subsided to normal size and consistency but the left only partially subsided and there are still pains occasionally and sometimes a milky secretion. When the mammae become hypertrophied without any connection with puberty or pregnancy, this generally happens in virgins of about 30. The hyper-

trophy may be up to nine years developing, and spontaneous retrogression has never been observed. The left mamma is the one usually involved or involved most. The hypertrophy of the mamma at puberty has not been known to retrogress spontaneously, but pregnancy hypertrophy develops more rapidly and usually subsides after delivery, but it may return with later pregnancies. With true hypertrophy of the mamma, the histologic findings suggest a pericanalicular fibroadenoma, but the slow growth and the diffuse enlargement differentiate it from cancer. The under side of the mamma may become excoriated and cases of erysipelas, abscesses and gangrene have been published, but no case is known of malignant degeneration. No medical treatment has ever been known to arrest the hypertrophy, not even treatment as for obesity, with loss of 10 per cent. of the weight. After resection of mamma tissue or skin, what is left continues to grow. Fixation of the pendent mamma to ribs or muscles has been tried and failed. The only operation that has proved successful is mastectomy. Roentgen treatment has been applied in two previous cases. In one the left mamma alone had hypertrophied and it subsided somewhat but returned during a pregnancy six years later, and mastectomy was done. The question now is what effect the roentgen treatment will have on lactation thereafter. Nunberg's experimental research demonstrated that the roentgen rays did not apparently modify the normal mammae of virgin animals examined after the animals were killed. By applying roentgen treatment in pregnancy hypertrophy, this question might be decided once for all.

Vaccination Against Typhus.—Thomsen reviews what has been done in this line in England and in Germany, saying that Neukirch seems to have had the best results with a vaccine made by rubbing smooth a blood clot in serum and then shaking with chloroform. He vaccinated 1,700 persons with this vaccine. Others have used a "vaccine" made with infected lice ground in a mortar with saline and injected subcutaneously. Three injections seemed to be complete protection for guinea-pigs, and might prove useful for especially exposed persons.

Ugeskrift for Læger, Copenhagen

May 22, 1919, 81, No. 21

*Gastric Secretion in Young Children. A. T. B. Jacobsen, p. 863.

Gastric Secretion in Young Children.—Jacobsen has been examining the gastric secretion in 25 children from 1 to 4 years old, forty-five minutes after a test meal of 20 gm. zwieback in 175 gm. water. There was no free hydrochloric acid to be found in over 50 per cent. and in all the children the proportion of acid and pepsin was below that of adults. In 2 of the 25 children there was no congo reaction at all. Both congo reaction and the Ginzburg were lacking in 5 of 6 children with acute gastro-intestinal disturbance, but as the latter subsided the gastric secretion returned to normal. This occurred likewise in 75 per cent. of the children with subacute and chronic gastro-intestinal disturbances with deficient gastric secretion. The diarrhea in both groups yields usually to a milk diet after preliminary restriction to water for half a day with 5 gm. castor oil.

SKILL AND SCHOLARSHIP AS IDEALS IN MEDICAL GRADUATE EDUCATION *

C. M. JACKSON, M.S., M.D.

MINNEAPOLIS

Even in ancient times, physicians recognized the advantages of a division of labor, allowing concentration of effort in a relatively narrow field of medicine. The ancient Babylonians, according to Garrison, had a physician for every disease, and in the Code Hammurabi (2250 B. C.) medical fees were already regulated by law. Likewise among the Egyptians, as shown by the Ebers papyrus, medicine was highly specialized as early as 1550 B. C. Herodotus states that in the fifth century B. C. (in Egypt):

Each physician applies himself to one disease only, and not more. All places abound in physicians; some physicians are for the eyes, others for the head, others for the teeth, others for the intestines, and others for internal disorders.

Although medical specialism was thus practiced by the ancients, who undoubtedly developed a high degree of skill in certain respects, for example, in operations for cataract by the Hindus, it soon reached its limits within comparatively narrow bounds. Throughout the ages, down to modern times, specialism, like medicine in general, made relatively slow progress, and for the same reason. The art of medicine necessarily remained empiric, awaiting the development of the fundamental sciences, physics, chemistry and biology. Before this, it was impossible for medicine to make real and rapid progress as an applied science.

With the rapid development of medicine during the past century, specialism has become increasingly necessary, since no man could possibly cover thoroughly more than a small portion of this immense field. While contributing greatly to the advancement of medicine, however, the increasing tendency to specialism in clinical medicine carries with it certain obvious disadvantages and dangers. From the point of view of the individual specialist, the tendency to narrowness through isolation is evident. From the point of view of the general public, the cost of medical service by isolated specialists is becoming burdensome, if not prohibitive.

These difficulties, both from the professional and from the economic point of view, present a serious

problem for consideration. The most promising solution appears to be the group system, whereby a staff of specialists may cooperate to practice medicine more efficiently. This means team-work associated with specialism, a principle which has been clearly realized and successfully carried out only in recent times. The Mayo Clinic is generally recognized as a pioneer in this work. The same principle has been followed with success in many other clinics, both public and private, and the movement is extending rapidly.

The tendency toward the group system in medical practice will doubtless receive an immense impetus from the experience during the war, as has been emphasized recently by Dodson. The excellent results obtained by this system in the numerous military and naval hospitals is an object lesson on a scale hitherto unknown. The thousands of medical practitioners who have thereby learned the increased efficiency of military medicine under this plan will doubtless desire to continue it on returning to civil practice. On the other hand, the advantages of the plan will not be lost on the millions of soldiers and sailors, who will naturally demand similar provision for medical service on their return to civil life. We may therefore expect in the near future to see medical groups organized for this purpose in every community able to support a hospital.

It is unquestionably true that preventive medicine will become increasingly prevalent, but this will by no means tend to minimize the importance of the group system. Public hygiene and sanitation likewise can be administered best by an organization of experts in various lines who must cooperate in the solution of the problems of preventive medicine. Moreover, by no means all forms of disease are preventable, even in theory. Curative medicine must therefore remain important, whether under private or state administration, and will certainly reach its greatest efficiency under the group system of organization.

Since well trained specialists are essential to the success of this plan, we may anticipate an increasing demand for them in the near future. Here also the war has revealed our present deficiencies. As Munson, Bispham and others have noted, a large proportion of our alleged specialists were found more or less incompetent in the military medical service.

Our present supply of real specialists thus is far below that indicated by the medical directory. In ophthalmology, for example, according to data cited by Reber, there are now in the United States about 5,000 listed ophthalmologists, of whom perhaps one fourth are really competent specialists. Edward Jackson estimates that about 10,000 trained ophthalmologists are needed in this country, or one to every 10,000 of population. Even if this number of ophthalmologists were now available, it is estimated that about 400

* Read at a meeting of the staff and students of the Mayo Foundation for Medical Education and Research at Rochester, Minn., April 23, 1919.

* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of references and other matter. The complete article appears in the author's reprints.

new men should be added each year in order to keep up the supply. The demand for well trained specialists in other lines is equally great.

To meet this demand, how are the specialists to be trained? In the first place, the plan of gradually narrowing from a general practice to a special field, a favorite method in the past, is now recognized as totally inadequate, unless supplemented by special training. For this special training, the opportunities offered by hospitals must be considered. Those hospitals with sufficient clinical facilities and with staffs efficiently organized are able to offer attractive educational opportunities to younger men who are willing to act as assistants during their period of apprenticeship. As has been pointed out by Welch, Barker and others, such positions as those of resident physician or surgeon in some of the larger hospitals represent, up to the present time, the best opportunities for capable young men who are ambitious to rise to eminence in the various phases of clinical medicine. Warner has recently emphasized the opportunities and responsibilities of the hospitals in the education of clinical specialists.

Unfortunately, such opportunities for hospital positions are now very limited in number, as well as defective in most cases from the educational point of view. This becomes apparent when one asks: "What training is needed for those who desire to attain leadership as clinical specialists in surgery, internal medicine, pediatrics, obstetrics, ophthalmology or other departments?" For the ideal education of specialists in medicine, the following conditions appear to me essential: (1) an adequate general medical education, including a hospital internship; (2) advanced work in the fundamental sciences; (3) advanced clinical instruction and training in the desired specialty; (4) training in research methods, and (5) adequate certification of proficiency. Let us consider these principles and the possibility of their realization under present conditions.

PRELIMINARY MEDICAL EDUCATION

An adequate general medical education is clearly an indispensable prerequisite for training in any branch of medical specialization. With a weak foundation, there can be no satisfactory superstructure. A graduate of a poor medical school cannot hope to become a competent specialist, unless he is willing first to go back and rebuild his primary medical education. Cases in which native genius is able to overcome the barrier of deficient preliminary education are rare.

Furthermore, a general hospital internship for at least a year, now recognized as an essential prerequisite for general practice, is even more important to give the broad, comprehensive clinical knowledge necessary for successful specialism. A narrow specialism will inevitably defeat its own ends. To avoid this obvious danger, the tradition still generally current in the medical profession requires several years of preliminary general practice. Recently, however, there has been marvelous improvement in clinical instruction in the better medical schools, making it possible (as Edward Jackson, Todd and others have pointed out) for the student to secure a better all-round clinical training by the end of his intern year than could formerly be obtained by several years of general practice.

There are certainly good educational and social reasons why the graduate medical training for specialism should begin as soon as possible. The graduate

of five or ten years' standing has lost much of his mental elasticity, and usually finds it very difficult to resume serious and intensive study. A graduate of a first-class medical school, with a subsequent hospital internship, may therefore safely proceed at once to the desired line of specialization.

ADVANCED WORK IN THE FUNDAMENTAL SCIENCES

Following his hospital internship, the first step needed by the prospective specialist is to strengthen his knowledge of the fundamental sciences underlying the clinical application in his chosen field. This principle must be emphasized, as it is frequently overlooked or ignored.

Nowadays a preliminary undergraduate training in the fundamental sciences of anatomy, physiology and pathology is universally recognized as essential for ordinary medical practice. But it is often forgotten that within the necessarily brief time allotted to these laboratory subjects in the medical curriculum, only their most elementary phases can be considered. These may be sufficient for the general practitioner, but are certainly inadequate for the specialist. Just as a general knowledge of the basic sciences is essential to their successful application in general practice, so is a more detailed first-hand knowledge of the underlying sciences equally necessary for intelligent specialization in a narrower clinical field. The logical graduate medical course must therefore repeat the order of sequence well recognized in the undergraduate curriculum: first, the fundamental sciences; second, their clinical application. The wouldbe specialist is prone to put the clinical cart before the laboratory horse, however, just as the shortsighted medical freshman undergraduate would like (and formerly was permitted) to attend clinics from the beginning of the medical course.

The principle that clinical medicine is an applied science is thus even more true for specialism than for general practice. Before the wouldbe clinical specialist has acquired a more thorough knowledge of the corresponding fundamentals, he simply does not have the science to apply. Without this science, the resultant training and practice will be empiric rather than scientific. Until this elemental principle is clearly recognized, we cannot hope for a satisfactory solution of the problem of graduate medical education for specialism. "Back to the laboratory" must be the slogan for the wouldbe specialist in the first stage of his graduate training.

Granting the principle, where can the requisite fundamental science be obtained? Practically the only places where the necessary facilities are now available are the laboratories of the medical schools of the stronger universities. Some of the larger hospitals have fairly good laboratories of pathology and bacteriology, but few have any one available who is capable of guiding the candidate in a systematic advanced study, even where there are laboratory facilities. The other laboratories necessary for graduate training are not provided by hospitals.

On account of the great expense involved, it likewise appears utterly impossible for the independent post-graduate medical schools to establish satisfactory laboratories for advanced scientific work. While these schools may serve a useful purpose in functioning as "undergraduate repair shops" (Flexner), their facilities for the adequate training of competent specialists are decidedly limited.

Even the universities which have adequate laboratory staffs and facilities for this purpose have rarely given much thought to the matter of providing the opportunities necessary for the training of clinical specialists in the fundamental sciences. Careful planning is required to give the best results. The course for each student should be arranged by conference between those in charge of the various clinical specialties and those in charge of the corresponding laboratory subjects involved. The essential point is that each student should have his work well outlined and supervised and that he should be provided with the necessary laboratory material and facilities.

Systematic provision should be made in a larger number of universities for at least this fundamental laboratory training needed by clinical specialists. Even the two-year medical schools, or other schools lacking sufficient clinical facilities for complete graduate training, could without much difficulty organize an excellent year's fundamental course for this purpose. A discussion of the curriculum requirements for graduate training in the various specialties may be found in papers by Todd, Sedgwick, Litzenberg, Edward Jackson, Duane, Shambaugh, Wishart and others. The broader phases of the subject are emphasized by Christian, Barker, Lyon and Wilson.

If the student could also have an opportunity to serve as a teaching assistant in one of the fundamental laboratories during the earlier part of his graduate work, so much the better. The road to specialization through an apprenticeship in one of the basic sciences, long recognized in Europe, has thus a substantial justification. As Melzer has well said:

The best physician of the future will be the brainy man who has spent many years in studying the methods employed in acquiring knowledge in the pure medical sciences, and then in applying all his mental energies to a broad study of disease.

The clinical graduate student should also profit greatly from his association with the laboratory sciences in ways other than the acquisition of indispensable information. He should also obtain what is really even more important, an inspiration of scientific ideals and a preliminary training in scientific methods. He should furthermore avoid the fallacious idea that he can leave the laboratory behind him when he has finished therein his preliminary training. Rather will he find it necessary, if his clinical career is to be progressive and fruitful, to maintain permanent relations with the basic medical sciences. Unless he catches the scientific spirit, and realizes that all medicine is essentially merely one phase of biology in a broad sense, his sojourn in the laboratory will have been in vain.

CLINICAL TRAINING FOR SPECIALISM

Following the preparatory work in the fundamentals, the clinical training for specialism is naturally of paramount importance. The apprenticeship method by which most specialists in the past have obtained this training in connection with private or public clinics has varied exceedingly in the opportunities offered and the results obtained. At best, while offering excellent practical training, it has usually been deficient in the requisite fundamental laboratory instruction above mentioned. Moreover, it has usually tended to become more or less routine in character, particularly when there is a large volume of clinical work to be done, with an inadequate number of assistants.

The objections to overloading the student with routine clinical work (during the internship) are thus emphasized by Dodson:

The amount of routine work now demanded of the intern in many hospitals so consumes his time as to make it very difficult and often impossible for any but the exceptional student to prepare a thesis. This ought not, however, so to be. The intern should have time to study the cases assigned to him thoroughly and carefully, and also pursue exhaustively the study of some disease or condition as presented by some interesting case, or group of cases, to explore the literature relating to that topic, and to set down in orderly fashion the results of his investigation. No instruction or experience in his career is so potent an educational measure as this one of independent creative work.

The argument naturally applies even more strongly in the cases of graduate students beyond the internship year who are preparing themselves to qualify as specialists.

Even in our own university work, where the educational principles are especially emphasized, the graduate fellows in clinical departments have sometimes found that the large amount of routine work they are required to perform leaves insufficient time and energy for the study necessary to meet the requirements of the graduate school.

While on the one hand a thorough, practical training in the clinical work is indispensable, it is clearly evident that this phase of the work may easily be over-emphasized, leading to a neglect of the scholarship requirements.

REQUIREMENTS IN SCHOLARSHIP

The question may fairly be raised as to whether these scholarship requirements are really necessary for those seeking to qualify for leadership in clinical specialism. Or are these requirements merely "academic frills" of no real value? The requirements are based on the theory that technical proficiency alone is insufficient to train the highest type of physician; that practical experience must be supplemented by theoretical study; that the ideal of skill must be accompanied by the ideal of scholarship, if we are to train clinical specialists of the highest type, who can render the greatest service to mankind, in research as well as in practice. Let us see whether there is any adequate basis for these assumptions.

From the broader point of view, considering education as the sum total of all factors which train man for better adjustment with his environment, both skill and scholarship are essential. Activity without intelligence is as fruitless as intelligence without activity. Knowing and doing must go hand in hand, if education is to be efficient. This principle is now generally recognized in undergraduate medical education. Is not the power of independent thought and productive scholarship even more important in graduate medical education? On this principle are based the graduate school requirements of thesis, foreign language and history of medicine. Let us briefly consider each of these in turn. The thesis involves a thorough training in scientific research methods, and the application of these methods in the solution of some medical problem. The emphasis on this phase of graduate work, this training in productive scholarship, seems to me justified in two ways.

In the first place, we all recognize that, in spite of great advances in the past, medical science is only at the threshold of its future possibilities. Suffering

humanity cannot wait for medical discoveries to come by chance. The state should therefore encourage and train research workers in every branch of clinical medicine, as well as in the more fundamental sciences. This is, I believe, the highest function of the university graduate school. Although only a few of the graduate students will actually develop into investigators of the first rank, even these few will fully justify all the effort and expense involved in their education. While the skilled specialist in his practice may relieve hundreds, his research resulting in even a comparatively small advancement in his subject will, through the entire medical profession, reach and benefit thousands and millions of human beings.

In the second place, training in research methods, as involved in the preparation of a creditable thesis, is also exceedingly valuable even for the larger number who will never become primarily researchers (in the narrower sense), but who will rather devote themselves to specialized clinical practice.

As Allbutt reminds us:

We are prone to forget that research has two purposes, results being but one of them; the other purpose is method, which is itself an education in flexibility, ingenuity, dexterity and perseverance.

Even the "purely clinical" specialist will thus profit greatly by a thorough training in scientific research methods. This training in research methods is directly beneficial to the clinical practitioner because the practice of medicine is, or should be, essentially scientific research. As Barker expresses it:

Each new patient is a problem for investigation; the clinician applies the methods he has learned and tries to solve it.

The importance of the research spirit in medical education has likewise been emphasized by Pearce and others. In its broader aspects, this subject is receiving increasing recognition as a principle of education in general, and may, let us hope, be extended throughout our entire educational system, from the kindergarten to the university. From this broader point of view, Donaldson's conception of the research spirit may be cited:

Research is a frame of mind. A man may have little leisure and trifling resources, may never have published, but if he examines his world in a questioning spirit, if he carries with him not only conclusions, but the observations on which they rest, if he refuses to pommel square facts into the round holes that he happens to have in hand, he has attained illumination. The spirit of research is nothing mysterious or remote; it is everyday hard sense. Unfortunately, that does not make it common, but it does make it attainable.

I have dwelt thus somewhat at length on the research spirit, because if it is so important to medicine in general, it should clearly be a very essential part of the highest phase of medical education, the graduate training of specialists. And the thesis is merely the concrete evidence that the student has caught the research spirit, that he has had adequate training in research methods and in their successful application in the solution of some definite medical problem.

As a corollary to the thesis requirement comes the necessity for a study of the medical literature. This involves a reading knowledge of the principal foreign languages. One foreign language is already an admission requirement to the undergraduate work in medical schools of the better class. The addition of a reading

knowledge in the second foreign language is not a burdensome requirement, and is an essential prerequisite for efficient scholarship. It is evident that one cannot well invade the unknown until he has learned what is already known in that particular phase of the subject. To do this, he should be able to read at least the three modern languages (English, French and German) in which the greater part of the original work in medical science is published. Translations are usually inadequate and frequently unavailable, even in abstract.

Even the genius of John Hunter did not prevent him from serious error (as cited by Jacobi) in denying the occurrence of visceral syphilis, which had already been demonstrated by Morgagni and Paracelsus. Numerous similar instances could be cited in every branch of medicine, indicating the necessity of a reading knowledge of foreign languages for efficient medical research. A knowledge of languages is necessary even for practitioners who desire merely to keep abreast of medical progress; and it is indispensable for those who aspire to leadership.

Associated with the thesis and language requirements is the subject of the history of medicine. Candidates for the higher degrees in medicine at Minnesota are required to know the history of medicine in general, and particularly that of the major subject in which the degree is sought. This requirement is based on the necessity for a background of historical knowledge, without which it is impossible to get an adequate conception of present conditions. The history of medicine teaches the evolutionary stages by which progress has been made in the past, and reveals pitfalls which must be avoided in the future. Probably in no department of human activity is a knowledge of its historical development more important than in medicine. The neglect of this subject in the undergraduate medical curriculum merely serves to emphasize the necessity for its requirement in the graduate work.

CERTIFICATION

It is not sufficient merely to provide adequate training for medical specialists. If they are to serve the public, some means must be devised to certify their proficiency. Realizing this necessity, the American Board for Ophthalmic Examinations (representing the national ophthalmic societies) examines those who have had the minimum training required for specialists in ophthalmology and awards certificates to those successful in passing the examination. Similarly membership in the American College of Surgeons indicates the recognition of ability in the practice of surgery. While certificates and titles of this character will undoubtedly be useful in helping to designate those at least moderately well qualified to practice in their special fields, it would seem that for those who have devoted a period of three years or more to a systematic course of graduate training and study a university degree is a more appropriate form of recognition and certification. No other institutions are so well qualified as the university to set standards which must command respect.

Just what this degree should be is a matter which has been much discussed, and concerning which there is still no unanimity of opinion. In the University of Colorado School of Medicine, where graduate work in ophthalmology has been developed through the pioneer efforts of Edward Jackson, the degree of Doctor of

Ophthalmology has been awarded to several candidates since 1913. Arnold proposes the degrees of Master of Science in Medicine (M.S.Med.) and Doctor of Science in Medicine (D.S.Med.), which in scholarship are essentially equivalent to the well known graduate degrees, Master of Arts (A.M.) and Doctor of Philosophy (Ph.D.). In addition, he proposes a degree of Doctor of the Practice of Medicine (D.P.Med.). "The requirements for this degree should be essentially the same as for the D.S.Med., except that the time devoted to research and to the preparation of a thesis would be devoted to the development of higher technic and skill in practice."

The latter proposal, to establish a practitioner's degree without research or thesis, is open to serious objections. It would tend to sacrifice scholarship in favor of skill, and thus to yield an unbalanced and undesirable type of specialism. Rather would it seem better to insist that no specialistic training without scholarship requirements involving at least some original work should be crowned by a university graduate degree.

Judging from our experience at Minnesota, graduate students in clinical branches will fall into three groups: Some will be unable to meet the thesis and associated requirements. This deficiency will debar them from being candidates for the higher degrees, irrespective of their technical skill in routine clinical work. Others will be able to produce a fairly creditable thesis, exhibiting some capacity for independent thought, though distinctly below the standard of scholarship ordinarily required for the doctor's degree in the graduate school. These may properly be awarded the degree of Master of Science (M.S.) in the special field. The third class, who measure fully up to the highest standards of both skill and scholarship, are awarded the degree of Doctor of Philosophy (Ph.D.) in the special field involved. We formerly awarded the degree of Doctor of Science (D.Sc.) for the same purpose, but abandoned it in recognition of the growing tendency to use this for an honorary degree.

The use of the M.S. and Ph.D. degrees (qualified or unqualified) for graduate work in the medical sciences is in accordance with the recommendations of the Committee on Degrees (A. C. Eycleshymer, chairman) at the recent meeting of the Association of American Medical Colleges in Chicago in March, 1919. The Ph.D. degree, as pointed out by Shambaugh, Vincent, Lyon and others, has the advantage of being thoroughly established, carrying with it everywhere the certification of ability in original thought and training in scientific methods. The qualification of the degree by the addition of the special field of clinical medicine involved should add to this a further recognition of practical ability in that professional field. It should indicate to the world that the recipient of this degree has undergone a long and careful training, both theoretical and practical; that he has met the most rigid tests both of skill and of scholarship; and that he is well qualified for leadership in his chosen field of specialism in medicine.

CONCLUSIONS

We must recognize an increasing need for medical specialism, especially in connection with the development of the group system in medical practice. For the training of efficient specialists, adequate facilities are in general available only in the medical schools of

the stronger universities. These schools should organize graduate work for systematic training of medical specialists along broad lines, including the necessary foundation in fundamental scientific work, practical clinical instruction and training in research methods. Work thus planned in accordance with the ideals of skill and scholarship will yield the most efficient type of specialist. Successful candidates may approximately receive the degree of Master of Science or Doctor of Philosophy, specifying the field of proficiency.

EXPERIMENTS TO DETERMINE MODE OF SPREAD OF INFLUENZA *

MILTON J. ROSENAU, M.D.

BOSTON

The experiments here described were performed on an island in Boston Harbor, on volunteers obtained from the Navy. The work was conducted by a group of officers detailed for that purpose, from the U. S. Navy and the U. S. Public Health Service, consisting of Dr. G. W. McCoy, director of the Hygienic Library, Dr. Joseph Goldberger, Dr. Leake, and Dr. Lake, all on the part of the U. S. Public Health Service; and cooperating with those medical officers, was a group also detailed for this purpose on the part of the U. S. Navy, consisting of Dr. J. J. Keegan, Dr. De Wayne Richey and myself.

The work itself was conducted at Gallops Island, which is the quarantine station of the Port of Boston, and peculiarly well fitted for operations of this kind, serving adequately for the purposes of isolation, observations, and maintenance of the large group of volunteers and personnel necessary to take care of them.

The volunteers were all of the most susceptible age, mostly between 18 and 25, only a few of them around 30 years old; and all were in good physical condition. None of these volunteers, 100 all told in number, had "influenza;" that is, from the most careful histories that we could elicit, they gave no account of a febrile attack of any kind during the winter, except a few who were purposely selected, as having shown a typical attack of influenza, in order to test questions of immunity, and for the purpose of control.

Now, we proceeded rather cautiously at first by administering a pure culture of bacillus of influenza, Pfeiffer's bacillus, in a rather moderate amount, into the nostrils of a few of these volunteers.

These early experiments I will not stop to relate, but I will go at once to what I may call our Experiment I.

EXPERIMENTS AT GALLOPS ISLAND

As the preliminary trials proved negative, we became bolder, and selecting nineteen of our volunteers, gave each one of them a very large quantity of a mixture of thirteen different strains of the Pfeiffer bacillus, some of them obtained recently from the lungs at necropsy; others were subcultures of varying age, and each of the thirteen had, of course, a different history. Suspen-

* Read before the joint meeting of the Section on Pharmacology and Therapeutics, the Section on Pathology and Physiology and the Section on Preventive Medicine and Public Health at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

* This paper and those by Drs. Frost, Park and Ganner, which follow are part of a symposium on "Influenza." The remaining papers and the discussion will appear in the issues for August 9 and 16.

sions of these organisms were sprayed with an atomizer into the nose and into the eyes, and back into the throat, while the volunteers were breathing in. We used some billions of these organisms, according to our estimated counts, on each one of the volunteers, but none of them took sick.

Then we proceeded to transfer the virus obtained from cases of the disease; that is, we collected the material and mucous secretions of the mouth and nose and throat and bronchi from cases of the disease and transferred this to our volunteers. We always obtained this material in the same way: The patient with fever, in bed, has a large, shallow, traylike arrangement before him or her, and we washed out one nostril with some sterile salt solution, using perhaps 5 c.c., which is allowed to run into this tray; and that nostril is blown vigorously into the tray. This is repeated with the other nostril. The patient then gargles with some of the solution. Next we obtain some bronchial mucus through coughing, and then we swab the mucous surface of each nares and also the mucous membrane of the throat. We place these swabs with the material in a bottle with glass beads, and add all the material obtained in the tray. This is the stuff we transfer to our volunteers. In this particular experiment, in which we used ten volunteers, each of them received a comparatively small quantity of this, about 1 c.c. sprayed into each nostril and into the throat, while inspiring, and on the eye. None of these took sick. Some of the same material was filtered and instilled into other volunteers but produced no results.

Now, I may mention at this point that the donors were all patients with influenza in Boston hospitals; sometimes at the U. S. Naval Hospital at Chelsea, sometimes at the Peter Bent Brigham Hospital, where we had access to suitable cases. We always kept in mind the fact that we have no criterion of influenza; therefore I would like to emphasize the fact that we never took an isolated case of fever, but selected our donors from a distinct focus or outbreak of the disease, sometimes an epidemic in a school with 100 cases, from which we would select four or five typical cases, in order to prevent mistakes in diagnosis of influenza.

Now, thinking that perhaps the failure to reproduce the disease in the experiments that I have described was due to the fact that we obtained the material in the hospitals in Boston, and then took it down the bay to Gallops Island, which sometimes required four hours before our volunteers received the material, and believing that the virus was perhaps very frail, and could not stand this exposure, we planned another experiment, in which we obtained a large amount of material, and by special arrangements, rushed it down to Gallops Island; so that the interval between taking the material from the donors and giving it to our volunteers was only one hour and forty minutes, all told. Each one of these volunteers in this experiment, ten in number, received 6 c.c. of the mixed stuff that I have described. They received it into each nostril; received it in the throat, and on the eye; and when you think that 6 c.c. in all was used, you will understand that some of it was swallowed. None of them took sick.

Then, thinking perhaps it was not only the time that was causing our failures, but also the salt solution—for it is possible that the salt solution might be inimical to the virus—we planned another experiment,

to eliminate both the time factor and the salt solution, and all other outside influences. In this experiment we had little cotton swabs on the end of sticks, and we transferred the material directly from nose to nose and from throat to throat, using a West tube for the throat culture, so as to get the material not only from the tonsils, but also from the posterior nasopharynx.

We used nineteen volunteers for this experiment, and it was during the time of the outbreak, when we had a choice of many donors. A few of the donors were in the first day of the disease. Others were in the second or third day of the disease. None of these volunteers who received the material thus directly transferred from cases took sick in any way. When I say none of them took sick in any way, I mean that after receiving the material they were then isolated on Gallops Island. Their temperature was taken three times a day and carefully examined, of course, and under constant medical supervision they were held for one full week before they were released, and perhaps used again for some other experiment. All of the volunteers received at least two, and some of them three "shots" as they expressed it.

Our next experiment consisted in injections of blood. We took five donors, five cases of influenza in the febrile stage, some of them again quite early in the disease. We drew 20 c.c. from the arm vein of each, making a total of 100 c.c., which was mixed and treated with 1 per cent. of sodium citrate. Ten c.c. of the citrated whole blood were injected into each of the ten volunteers. None of them took sick in any way. Then we collected a lot of mucous material from the upper respiratory tract, and filtered it through Mandler filters. While these filters will hold back the bacteria of ordinary size, they will allow "ultramicroscopic" organisms to pass. This filtrate was injected into ten volunteers, each one receiving 3.5 c.c. subcutaneously, and none of these took sick in any way.

The next experiment was designed to imitate the natural way in which influenza spreads, at least the way in which we believe influenza spreads, and I have no doubt it does—by human contact. This experiment consisted in bringing ten of our volunteers from Gallops Island to the U. S. Naval Hospital at Chelsea, into a ward having thirty beds, all filled with influenza.

We had previously selected ten of these patients to be the donors; and now, if you will follow me with one of our volunteers in this ward, and remember that the other nine were at the same time doing the same thing, we shall have a picture of just what was happening in this experiment:

The volunteer was led up to the bedside of the patient; he was introduced. He sat down alongside the bed of the patient. They shook hands, and by instructions, he got as close as he conveniently could, and they talked for five minutes. At the end of the five minutes, the patient breathed out as hard as he could, while the volunteer, muzzle to muzzle (in accordance with his instructions, about 2 inches between the two), received this expired breath, and at the same time was breathing in as the patient breathed out. This they repeated five times, and they did it fairly faithfully in almost all of the instances.

After they had done this for five times, the patient coughed directly into the face of the volunteer, face to face, five different times.

I may say that the volunteers were perfectly splendid about carrying out the technique of these experiments. They did it with a high idealism. They were inspired with the thought that they might help others. They went through the program

in a splendid spirit. After our volunteer had had this sort of contact with the patient, talking and chatting and shaking hands with him for five minutes, and receiving his breath five times, and then his cough five times directly in his face, he moved to the next patient whom we had selected, and repeated this, and so on, until this volunteer had had that sort of contact with ten different cases of influenza, in different stages of the disease, mostly fresh cases, none of them more than three days old.

We will remember that each one of the ten volunteers had that sort of intimate contact with each one of the ten different influenza patients. They were watched carefully for seven days—and none of them took sick in any way.

EXPERIMENTS AT PORTSMOUTH

At that point, the holidays came, our material was exhausted, and we temporarily suspended our work. In fact, we felt rather surprised and somewhat perplexed, and were not sure as to the next way to turn, and we felt it would be better to take a little breathing spell and a rest.

We started another set of experiments in February that lasted into March, again using fifty volunteers carefully selected from the Deer Island Naval Training Station. These experiments I will not give in detail. They would take too long. They were simply designed and the program was carefully planned, but the way matters turned out became very confusing and perplexing. I will give two instances to explain what I mean by that; and I give them because they are exceedingly instructive and very interesting.

In February and March, the epidemic was on the wane. We had difficulty in finding donors. We were not sure of our diagnosis, having no criterion of influenza. We therefore felt very fortunate when we learned of an outbreak that was taking place at the Portsmouth Naval Prison, only a few hours north of Boston. We at once loaded a couple of automobiles filled with our volunteers, and rushed up to Portsmouth, and there repeated many things that I have described in our first set of experiments. At Portsmouth, out of a large number of cases, we made our selections carefully, taking the typical cases for donors, and transferring the material directly to our volunteers. In about thirty-six hours, half of the number we exposed came down with fever and sore throat, with hemolytic streptococci present, and doubtless as the causal agent. All the clinicians who saw these cases in consultation agreed with us that they were ordinary cases of sore throat.

Another incident: One of our officers, Dr. L., who had been in intimate contact with the disease from early in October, collected material from six healthy men at the Portsmouth Navy Yard who were thought might be in the period of incubation of the disease—we were trying to get material as early as possible, because all the evidence seems to indicate that the infection is transmissible early in the disease. None of the six men came down with influenza, but Dr. L. came down in thirty-six hours, with a clinical attack of influenza, although he had escaped all the rest of the outbreak.

CONCLUSION

I think we must be very careful not to draw any positive conclusions from negative results of this kind. Many factors must be considered. Our volunteers may not have been susceptible. They may have been immune. They had been exposed as all the rest of the

people had been exposed to the disease, although they gave no clinical history of an attack.

Dr. McCoy, who with Dr. Richey, did a similar series of experiments on Goat Island, San Francisco, used volunteers who, so far as known, had not been exposed to the outbreak at all, also had negative results, that is, they were unable to reproduce the disease. Perhaps there are factors, or a factor, in the transmission of influenza that we do not know.

As a matter of fact, we entered the outbreak with a notion that we knew the cause of the disease, and were quite sure we knew how it was transmitted from person to person. Perhaps, if we have learned anything, it is that we are not quite sure what we know about the disease.

[A complete account of the experiment is being published by the U. S. Public Health Service.]

THE EPIDEMIOLOGY OF INFLUENZA *

W. H. FROST, M.D.

Surgeon, U. S. Public Health Service
WASHINGTON, D. C.

The history of influenza so far as it is known, that is, for several centuries, comprises a series of long cycles in which great pandemics alternate with periods of relative quiescence, the length of cycles as measured by the intervals between pandemics being usually a matter of decades. The special characteristics of influenza pandemics are their wide and rapid extension, their high attack rates, and great effect on general mortality rates. Since these cycles are undoubtedly of fundamental significance in the natural history of influenza any proper discussion of the epidemiology of the disease should cover at least one full cycle, preferably the last, from 1889 to the present. The material for such a discussion must, however, be collected from many and diverse sources and laboriously fitted together, since there is no concrete specific and continuous record of the prevalence or mortality of influenza during such a period of years.

LACK OF SPECIFIC RECORDS

During great epidemics there are abundant, if not exact records of prevalence, and the resulting mortality can be determined with fair precision, even though a large proportion of the deaths are classified under diagnoses other than influenza. In the intervals between epidemics influenza becomes inextricably confused with other respiratory diseases, having a general clinical resemblance but no definite etiologic entity, so that the record of prevalence and even of mortality is virtually lost. The first requisites for epidemiologic study; namely, clear differential diagnosis and systematic records of occurrence, are therefore lacking in influenza.

In the absence of these essential records, statistics of mortality from the group comprising influenza and all forms of pneumonia afford, perhaps, the nearest approximation to a record of influenza. It is not intended to suggest that the mortality from this group of diseases furnishes in any sense a *measure* of the prevalence of influenza, but only that it furnishes an

* Read before the joint meeting of the Section on Pharmacology and Therapeutics, the Section on Pathology and Physiology and the Section on Preventive Medicine and Public Health at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

index, since it is well established that the epidemic prevalence of influenza markedly affects the mortality from this group of diseases, and since it is at least probable that, even in nonepidemic periods, there may be some intimate and constant relation between the prevalence of influenza and the mortality from pneumonia.

The following discussion, which is necessarily confined to a few broad outlines, is accordingly based on records of mortality from influenza and pneumonia for a series of years; statistics of general mortality during the recent epidemic, and limited morbidity statistics.

INFLUENZA AND PNEUMONIA MORTALITY IN MASSACHUSETTS, 1887-1916

Table 1 and Chart 1 show for Massachusetts, a state in which continuous records are available, the number of deaths and the death rates per hundred thousand from influenza and from all forms of pneumonia, by months, from 1887 to 1916, inclusive.

Chart 1 shows clearly the effect of the epidemic of 1889-1892, developing in three distinct phases, the first phase culminating in January, 1890; the second in

April and May, 1891; and the third in January, 1892. It will be noted that the mortality was higher in 1891 than in 1890, still higher in 1892, and that in 1893, although no distinct epidemic occurred, the pneumonia mortality for the year was still higher than in 1892. This corresponds to the experience in England according to Parsons,¹ and apparently represents the

general experience in other countries, with some differences in chronology and relative severity of the several phases of the epidemic.

COMPARABLE STATISTICS FOR 1910-1918

As comparable statistics for Massachusetts in 1917 and 1918 are not now at hand, it is necessary to turn to other sources for the record of these years. The U. S. Census Bureau has very kindly furnished to me, from tables prepared for publication in the 1917 mortality statistics, the number of deaths by months during 1917 from pneumonia and influenza in certain registration states

and registration cities of over 100,000 population, thus continuing through that year the records of monthly

1. Parsons, H. Franklin: A Further Report on the Influenza Epidemics of 1889-90, 1891 and 1891-92, Local Government edition, London, 1893.

TABLE 1.—DEATH RATES PER HUNDRED THOUSAND OF POPULATION, FROM PNEUMONIA (ALL FORMS) AND FROM INFLUENZA, IN MASSACHUSETTS, 1887-1916, INCLUSIVE.*

* Compiled from number of deaths as given in Registration Reports, State of Massachusetts, 1887-1916, except data for 1912, from Mortality Statistics U. S. Census Bureau.

mortality available from published mortality statistics from 1910 to 1916, inclusive; and has also furnished records of deaths in certain of these states and cities, by months, during 1918. The latter figures were compiled and submitted by state and local registrars in compliance with a special request from the director of the census. They are merely provisional and the Census Bureau in no way vouches for their accuracy; but they are believed to be sufficiently exact for present purposes.

Owing to limitations of space, the statistics of only three cities (New York, Cleveland and San Francisco) are presented here. These are, however, fairly representative of the whole group of cities and states for which records are at hand. As may be seen from Table 2 and Chart 2, the mortality from influenza and pneumonia in these cities was fairly regular from 1910 till 1915, as was the case in Massachusetts (Chart 1) and generally throughout the registration area of the United States.

operation of some definite and wide-spread factor and suggesting in this group of diseases an epidemic tendency which is perhaps not sufficiently appreciated.

In *Public Health Reports* for Jan. 7, 1916, influenza was reported to be epidemic in twenty-three states in all sections of the United States, an epidemic now generally forgotten.

ANOTHER SHARP AND GENERAL RISE IN MORTALITY IN THE SPRING OF 1918

In the spring of 1918 there was another sharp and general rise in mortality from these diseases, clearly evident in Chart 2. In the larger cities on the Atlantic seaboard, this increase occurred generally during January, February and March, when pneumonia mortality normally reaches its maximum, and the increase was not so evident in all these cities as it was in New York City. In the rest of the country, especially in the central and western states, the increase occurred in April, a month during which pneumonia mortality is generally on the decline; and was sufficient to constitute an unmistakable departure from the normal. The increased mortality rate extended quite generally into May and in some areas still longer.

This occurrence has, I believe, a definite significance in relation to a coincident prevalence of influenza, and to the subsequent development of the influenza pandemic. Although there is no definite record of a gen-

Chart 2.—A. Annual death rates per hundred thousand from influenza and pneumonia (all forms), by months, 1910-1918, in three American cities.

SIGNIFICANT RISE IN MORTALITY IN DECEMBER, 1915

In December, 1915, and January, 1916, there occurred in New York and Cleveland a sudden sharp rise in mortality. This, though not shown distinctly in San Francisco, was almost universal and synchronous over the whole of the registration area. While this may have no direct significance in relation to the 1918 pandemic, it is at least of interest as indicating the

* Data for years 1910-1916 compiled from Mortality Statistics, U. S. Census Bureau, for those years; data for 1917 from table prepared for publication in 1917 Mortality Statistics, advance sheets being furnished by the Census Bureau; data for 1918 from special reports, rendered to Director of the Census by city registrars. Populations used are U. S. Census Bureau midyear estimates.

eralized epidemic of influenza in the United States in the spring of 1918, definite local outbreaks were observed at that time. For example, Vaughan and Palmer² have described a mild epidemic prevailing in the Oglethorpe camps in March. The commissioner of health of Chicago³ states, in his special report on the autumn epidemic in Chicago, that in March, 1918, distinct epidemics resembling influenza were observed in certain groups in that city. Stanley⁴ in a recent publication describes three epidemics of influenza occurring in April, October and November, 1918, respectively, in San Quentin prison, California. These three epidemics were quite

Chart 3.—Annual death rates from all causes, by weeks, March 2, 1918, to April 5, 1919, in forty-five American cities (population, 1918, 22,672,630) and ninety-six large cities of England and Wales (population, 1917, 16,577,344). Continuous line with circles signifies the forty-five American cities, and the broken line with solid dots the ninety-six large cities of England and Wales.

similar and that of April apparently developed from a newly received inmate, presumably infected in Los Angeles, indicating the presence of the infection there at that time.

Ogic, Freeman and others⁵ of the Army Commission, studying pneumonia at Camp Funston, found that recurrent outbreaks of pneumonia observed there in March, April and May, 1918, were definitely associated with coincident epidemics of a mild type of influenza.

The rise in mortality from this group of etiologically heterogeneous diseases in the spring of 1918, is so sudden, so marked, and so general throughout the United States as to point very clearly to the operation of a single definite and specific cause, something largely independent of meteorologic and other local conditions. The observed occurrence of local epidemics of influenza at that time in widely scattered localities, the intimate association established at Camp Funston between the epidemic of influenza and pneumonia, and the subsequent development of the influenza pandemic, all indicate that the increased pneumonia mortality of March and April, 1918, was the consequence of a beginning and largely unnoticed epidemic of influenza, the beginning in this country of the great pandemic which developed in the autumn.

MILD EPIDEMICS OF INFLUENZA IN EUROPE IN APRIL AND MAY, 1918

From various localities in western Europe mild epidemics of influenza are reported in April and May, 1918; and perhaps there may be earlier reports. During June and July extensive epidemics were reported

from Great Britain, various parts of continental Europe, China, India, the Philippine Islands and Brazil, with marked effect on general mortality rates in such of these countries for which records are available.

COURSE OF 1918 EPIDEMIC

The course of the epidemic in England and Wales, and in the United States, respectively, is illustrated by Chart 3, which shows the annual death rates from all causes, by weeks, in ninety-six large cities of England and Wales⁶ with an aggregate population (1917) of 16,577,344 and in forty-five large American cities⁷ aggregating about 22,950,000 population (1918).

In the British cities the epidemic has so far manifested three distinct waves: the first and slightest, in point of mortality, occurring in June and July; the second and most severe in November; the third in February and March. Data which need not be cited here in detail indicate that the course of the epidemic in western Europe, generally, was similar. In cities of India the sequence was similar but the mortality far greater. In the United States the epidemic developed more largely in a single wave, during September, October and November. If, however, the epidemic already mentioned as occurring in the spring be considered the first phase, and the explosive outbreak of the autumn, the second, a third phase or recrudescence is quite evident in many areas, though not shown distinctly in Chart 3, in which are combined a number of widely separated cities

Chart 4.—Annual death rates per thousand from all causes, by weeks, July 27, 1918, to April 5, 1919. The unbroken line is the record of Boston, the dash line of Washington, and the dot line of San Francisco.

September is already well known and need not be discussed here in detail. The prevalence of a serious epidemic among the civilian population was first recognized in and around Boston about the first of September. Within about two weeks the epidemic was

⁷ Weekly Health Index, U. S. Census Bureau, Washington, D. C.

general in cities on the Atlantic seaboard, developing a little later among the cities farther west. Rural districts were usually attacked somewhat later than large cities in the same sections. The sequence of the epidemic in three cities (Boston, Washington and San Francisco) is shown in Chart 4. The interval between the peaks of the epidemic in Boston and San Francisco is four weeks, which is approximately the maximum difference between any two large American cities in this phase of the epidemic.

CURVES OF MORTALITY IN VARIOUS AMERICAN CITIES

The curves of mortality differed widely in different cities, as illustrated in Chart 5, showing in Philadelphia a very

Chart 5.—Annual death rates per thousand from all causes, by weeks, July 27, 1918, to April 5, 1919. The unbroken line is the record of Philadelphia, the dash line of New York, and the dot line of St. Louis.

explosive and abrupt curve, observed more frequently among cities on the Eastern seaboard; in New York a less explosive curve, with a more prolonged high mortality rate, as observed more commonly in middle western cities, often with a more pronounced recrudescence; in Kansas City a still more gradual curve, declining only slightly after the first wave, and with a severe recrudescence, curves of this general character being more common in the middle west.

TOTAL NUMBER OF DEATHS AMONG THE CIVIL POPULATION

Based on incomplete statistics, which represent, however, all the main geographic divisions of the country, including both urban and rural populations, the deaths among the civil population of this country directly attributable to the epidemic are estimated at not less than 450,000, or more than 4.0 per thousand. This rate exceeds even a liberal estimate of the net excess mortality rate in Massachusetts during the four years (1890-1893) following the influenza outbreak in 1889-1890.

DIFFERENCE IN MORTALITY IN VARIOUS GEOGRAPHIC GROUPS

Classifying the forty-five cities of the Weekly Health Index into three broad geographic groups there is a noticeable difference in mortality. In the cities east of the line of the Appalachians, the excess mortality from pneumonia and influenza during the weeks end-

ing Sept. 14, 1918, to March 1, 1919,* was approximately 5.6 per thousand; in cities between the Rocky Mountains and the Appalachians, 4.35; and in those of the Pacific Coast, 5.55 per thousand.

Notwithstanding this general geographic relation, there are notably wide differences in the mortality rates of individual cities in the same section, even between cities close together, differences which are not as yet explained on the basis of climate, density of population, character of preventive measures exercised, or any other determined environmental factor.

More intimate details of epidemiology can be given only the briefest mention here. In order to secure reliable statistics of morbidity, the Public Health Service has made special house-to-house surveys in a number of localities,⁹ ascertaining the number of persons affected, the dates of onset and a few other simple facts in accurately enumerated groups representative of the general population. Partial analysis of the results of these surveys, in eight localities,¹⁰ giving an aggregate of 112,958 persons canvassed, show the following chief facts of interest:

RESULTS OF HOUSE-TO-HOUSE SURVEYS

The percentage of the population attacked varied from 15 per cent. in Louisville, Ky., to 53.3 per cent. in San Antonio, Texas, the aggregate for the whole group being about 28 per cent.¹¹ This agrees with scattered observations in the first phase of the 1889-1890 epidemic, when the attack rate seems to have varied within about these limits. The case incidence was found to be uniformly highest in children from 5 to 14 years old, and progressively lower in each higher age group. It was slightly higher in females than in males of corresponding age; usually higher in the white than the colored population.

The ratio of pneumonia cases to total population varied from 5.3 cases per thousand in Spartanburg to 24.6 per thousand in the smaller towns of Maryland.

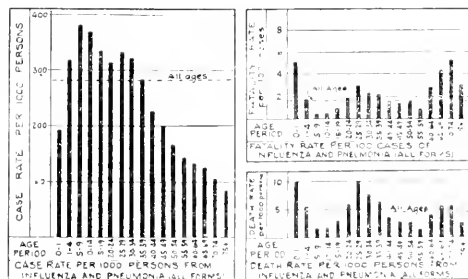

Chart 6.—Influenza records for 1918. Case rates, death rates and fatality rates among persons of different ages in certain areas surveyed in Maryland; San Antonio, Texas; San Francisco; New London, Conn.; Louisville, Ky.; Little Rock, Ark.; and Spartanburg, S. C.

The pneumonia rate showed little correlation with the influenza attack rate.

8. Summary, Influenza Epidemic, U. S. Census Bureau, Weekly Health Index, March 1.

9. For a description of methods and more detailed statistics of certain localities, compare Public Health Reports 34: 191 (March 14) 1919.

10. Data from surveys of population groups as follows: New London, Conn.; Baltimore; certain smaller towns and rural districts in Maryland; Spartanburg, S. C.; Louisville, Ky.; Little Rock, Ark.; San Antonio, Texas; San Francisco.

11. The surveys were made mostly during December, after the first wave of the epidemic had subsided, but before the second wave. Later figures would add somewhat to the incidence.

The ratio of deaths to population varied from 1.9 per thousand in Spartanburg to 6.8 in Maryland towns. The death rate was by no means parallel to the influenza attack rate, but was correlated closely with the pneumonia rate. In other words, the case fatality of pneumonia tended to be fairly constant, around 30 per cent., except in San Antonio, where it was only 18.5 per cent. The death rate was notably high in children under 1 year old, in adults from 20 to 40, and in persons over 60; higher in males than in females of comparable ages; higher in the white than in the colored.

The case fatality was likewise higher in these age groups: under 1 year, 20 to 40, and over 60 years; and it is this fact, rather than the incidence rates, which determines the death rates in different age groups.

Chart 6 shows the attack rates, death rates and case fatality rates in various age groups.

THE IMPORTANT QUESTION OF IMMUNITY

Concerning the important question of the immunity conferred by an attack of influenza, the evidence is not conclusive, chiefly because of the uncertain differentiation between influenza and other infections. Parsons, from his study of the last epidemic,¹ inclines to the view that an attack of influenza in the earlier years of the epidemic conferred a considerable but not absolute immunity in the later outbreaks.

In Baltimore, where our first canvass of 33,776 people was made between Nov. 20 and Dec. 11, 1918, a second canvass of the same population was made in January to determine the extent of the recrudescence reported in December. Among 32,600 people included in this canvass, 724 cases of influenza were found to have occurred since the previous survey. Of this number 121 cases were reported as second attacks, but on investigation through the attending physicians or by a medical officer, the clinical diagnosis of both attacks as influenza was confirmed in only 26 cases or 0.37 per cent. of the total, and even in these cases the diagnosis is necessarily uncertain. Considering that 23 per cent. of the population had had influenza prior to December 11, the proportion of second attacks should have been much greater if no immunity had been acquired. A second canvass in San Francisco gave generally similar results. The data collected for a study of this question from other angles have not yet been analyzed.

GENERAL CHARACTERISTICS OF EPIDEMIC

In general, this epidemic has been quite similar to that of 1889-1890 in its early development, first in mild, scattered outbreaks, later in a severe world-wide epidemic; in the rapidity of its spread, and in its high case incidence. It has been notably different in a much higher frequency of pneumonia and consequently much higher mortality, especially among young adults.

Such evidence as has been collected confirms the conclusion previously reached that the infection is transmitted directly by "contact" in the broad sense. It appears probable, however, that the infection was already widely disseminated in this country some time before a serious epidemic was recognized.

PROBABILITY OF RECURRENCES IN THE NEAR FUTURE

The question of most practical and immediate interest is the probability of recurrence in the near future. Recurrences are characteristic of influenza epidemics; and the history of the last pandemic and previous ones would seem to point to the conclusion that this one has not yet run its full course. On the other hand, this

epidemic has already shown three more or less distinct phases and has been more severe, at least in mortality, than the three-year epidemic of 1889-1892, facts which may justify the hope, though not the conclusion, that it has run its course already.

It seems probable, however, that we may expect at least local recurrences in the near future, with an increase over the normal mortality from pneumonia for perhaps several years; and certainly we should be, as far as possible, prepared to meet them, by previous organization of forces and measures for attempted prevention, treatment and scientific investigation.

FUTURE STUDY AND CONTROL

As regards preventive measures, the efficacy of those carried out in recent months is not proved, and we can only continue to follow the apparently sound principles already applied. It seems hardly logical to expect that any measure short of effective specific immunization will afford lasting protection to the general population; but we may perhaps hope to delay the spread of infection, thus affording better facilities for treatment of the sick, and this is an achievement well worth while.

With reference to scientific investigations, these should not be conditioned on recurrence of the epidemic. Now is the time to inaugurate comprehensive laboratory and field investigations of influenza and pneumonia, to be continued not for a few months, but for a series of years, since a knowledge of influenza during the intervals between epidemics is essential to the understanding of epidemics. In this connection one of the most essential requisites for a better understanding of the disease is better differential diagnosis of endemic influenza, with more careful observation and recording of the relatively mild, indefinitely diagnosed epidemics of supposed influenza which are noted from time to time in the intervals between definite epidemics. Even in the absence of a definite diagnosis of individual cases, much would be added to the history of influenza by describing such outbreaks more fully and making them matters of more general record.

BACTERIOLOGY OF RECENT PANDEMIC OF INFLUENZA AND COMPLICATING INFECTIONS*

WILLIAM H. PARK, M.D.

Director, Laboratories of New York City Health Department

NEW YORK

When the recent outbreak of influenza appeared, it was assumed by all that it was probably due to the same cause as that of 1889. Health officials, epidemiologists and bacteriologists, already overwhelmed by the demands of the war, were called on to investigate and combat the infection.

The first appearance of the epidemic was in Europe. Bacteriologists, while keeping an open mind, naturally first sought for the influenza bacillus isolated by Pfeiffer from endemic cases of influenza-like infections some two years after the 1889 epidemic.

He had established a relationship between this bacillus and infections of the respiratory tract and had assumed that it was the primary agent in the great

* Read before the joint meeting of the Section on Pharmacology and Therapeutics, the Section on Pathology and Physiology and the Section on Preventive Medicine and Public Health at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

pandemic. Investigations since then have thrown considerable doubt on this assumption, and many have now come to consider the bacillus as only one of several varieties of bacteria which have a special selective tendency to attack the mucous membranes of the upper respiratory tract.

The reports from different investigations in Europe have been most conflicting. Influenza bacilli were found in some localities to be present in nearly every case, while in others bacteriologists isolated them from only a small minority of the patients.

In their place, pneumococci, streptococci and gram-negative micrococci were found. Frequently, several varieties occurred together. A few observations in France and England indicated that a filtrable virus was present in at least some of the cases. As a filtrable virus had already been demonstrated in outbreaks of common colds, when no epidemic existed, this information, in spite of its great interest, simply added one more line of investigation.

The possibility that more than one epidemic of an influenza-like disease was prevailing in Europe makes it advisable to concentrate our attention on the results of the bacteriologic findings in this country. Here, the unity of the epidemic which swept over the land was unmistakable.

NECESSARY PROOF

To identify a micro-organism as the cause of a widespread epidemic, the germ must be capable of producing the type of disease under investigation; it must be present in the advancing area in all cases at the beginning of the infection, and in any outbreak it must have the same characteristics when freshly isolated from different patients. The repeated transfer of a pathogenic germ from patient to patient allows the most characteristic forms to increase, so that until an epidemic is on the wane we find that isolations from different cases from different localities are practically identical. When the different cultures are grown in artificial mediums, under suitable and similar conditions, the isolations from different sources will continue to hold their characteristics sufficiently to be studied and compared.

Even well trained bacteriologists frequently fail to realize that an epidemic strain is alike everywhere in cases belonging to the epidemic.

Before considering the results so far obtained and drawing our conclusions, let us consider for a moment the special problem before us. Epidemic influenza is a disease primarily attacking the respiratory passages. The symptoms during life and the lesions in the dead, although fairly distinctive in the cases at the height of the epidemic, are by no means so in those occurring after it has passed. Whatever the primary infecting micro-organism may be, there is no doubt that in most cases other pathogenic bacteria are decisively associated. Many of these produce very similar symptoms and lesions. It is perfectly possible that a strain of any one of these bacterial varieties may have increased in virulence to an extent enabling it to initiate an epidemic. The micro-organism responsible for the epidemic may either be a microbe hitherto unknown to us or to a new and more virulent strain of some known form. Even if we assume the latter alternative, we have a difficult problem to obtain the proof, for we must discover how to identify it as a new strain. Supposing that we had found pneumococci in all cases, but that in some we had isolated only Type I and in some only

Type II. Instead of this being evidence for a pandemic pneumococcus strain, it would be just the opposite, for two different strains cannot be responsible for one epidemic.

For our purpose, the two types are as distinct as if they were diphtheria and tubercle bacilli; and if either is the pandemic strain, it must occur in all the cases.

Suppose we find in every case a Type II pneumococcus. This is very suggestive, but it is really no proof unless we can show some peculiarity different from that in the cases of respiratory infections before the epidemic. Only then have we probably obtained the culprit. Because of the lack of this evidence, Pfeiffer made his hasty conclusion.

The most delicate test that we have for identity of strains is that animals injected with them produce identical antitoxins.

The resemblance between the agglutinins produced is usually selected as the best evidence of identity or dissimilarity. With the filtrable viruses we have to depend on finding some susceptible animal, or revert to human volunteers and if successful in producing infection, test for specific immunity.

RESULT OF RECENT INVESTIGATIONS

The pandemic of 1918 is over. The difficulty of being certain that any suspected cases are due to the pandemic virus is gradually increasing. It is probable that if we have not at the present time gathered sufficiently convincing evidence to convict some germ we shall have to wait for another epidemic to solve the problem. It will be well to summarize very briefly some representative investigations.

Kegan made cultures from a number of cases in the virulent outbreak at the First Naval District at Chelsea, Mass. Cultures from twenty-three cases gave influenza bacilli in nineteen, and in some no other bacteria were found. In four cases he considered a streptococcus of the hemolytic variety the dominant organism and in seven cases the influenza bacillus. The earlier the cultures were taken, the greater was the percentage of influenza bacilli.

Spomer, Scott and Heath found evidence that the cases reacted to the influenza bacillus invasion by the production of antibodies. At the end of the first week agglutinins appeared sufficiently in the blood of some cases to agglutinate influenza bacilli when in a 1:50 dilution. In five weeks the serum of some agglutinated when in a dilution of 1:800. They found no evidence of strains of influenza bacilli. They did not use the more delicate and accurate absorption methods in their tests. These investigations afforded evidence that in that extensive outbreak the influenza bacilli played an important part either as the primary agent or as a secondary invader. In four cases a hemolytic streptococcus was shown to play an important and even decisive part.

In the Central West, in twenty-three cases of acute influenza in the early stage, Opie, Freeman, Blake, Small and Rivers subjected the patients to examination and obtained influenza bacilli from all. The examination of the sputum from sixty-nine cases of pneumonia revealed influenza bacilli in forty-three.

Pneumococci were found in every case, but were of different types. The men named agree with Kegan as to the etiologic importance of the influenza bacillus in this epidemic. They place the sequence of events as follows: At the time of infection, *B. influenzae* descends into the bronchi; later, pneumococci may

invade the inflamed bronchi, enter the lung and produce either lobar pneumonia or bronchopneumonia. Hemolytic streptococci may at any time descend and infect the pneumonic lung.

Although Keegan, Opie and their associates believe that the influenza bacilli are the causative agent, they present no real evidence. Opie demonstrated in some groups of healthy soldiers, that 50 per cent. could be shown to harbor influenza bacilli. No proof was obtained that these bacilli differed in any way from those isolated from the patients. Their evidence is as strong that the bacilli are secondary invaders as that they were the primary ones.

In 278 cases occurring in New York, Williams found influenza bacilli as shown in Table 1.

TABLE 1.—EXAMINATION FOR INFLUENZA BACILLI.

Group	Influenza Bacilli Per Cent. Present
Hospital cases	80
Marines*	100
Home for children	98
Material examined:	
Lungs	80†
Tracheas	96
Heart's blood	10

*The marines came from different vessels.

†Seventeen per cent. in nine cultures.

We found that the best site for the material selected, the use of the best mediums and long training in the study of influenza colonies were important in finding the bacilli.

In 100 cases, among civil and soldier patients in Chicago, Nuzum, Pilot, Stangl and Bones found the results given in Table 2.

TABLE 2.—BACTERIA FROM SPUTUM, NASOPHARYNX AND TONSILS

	Pneu.	B. Inf.	St. Hem.	Mic. Cat.
	C.	C.	C.	C.
Washed bronchial sputum	70	4	20	5
Cultures from nasopharynx	38	0	7	5
Cultures from tonsils	74	0	37	7

Five healthy persons volunteered to be inoculated in the nostrils with the filtrate from infected mucus. A very slight coryza in one and a moderate attack in another resulted. They think the results insufficient to indicate the pandemic to be due to a filtrable virus. They believe that in their cases pneumococci of unusual virulence were the most important early secondary invaders. Influenza bacilli were less important than many other bacteria.

Lamb and Brannin, at Camp Cody, Deming, N. M., found in pneumonia, in sputum specimens, the bacteria as shown in Table 3.

TABLE 3.—BACTERIA PRESENT IN PNEUMONIA*

	Cases	Per Cent.
Pneumococcus (all types, but chiefly Type IV)	310	89.1
Streptococcus (one third hemolytic types)	222	63.5
B. influenzae	99	27.9
M. catarrhalis	21	6

*Blood agar was used for platings.

A careful survey of all the literature leaves the same impression as that left by the brief summary of the few representative investigations I have just given.

There is no proof that any one germ is present in all cases. The influenza bacillus has the lead among the possibilities, partly because of its historical position and partly because, as it requires much training to isolate it from a mixture of other bacteria, the thought remains in the minds of many that the failure to obtain it in some outbreaks is due, not to its absence, but to lack of training in the bacteriologist seeking it.

If isolations from a number of cases proved to have identical characteristics, the probability that the influ-

enza bacillus was the cause of the epidemic would be great, while if many strains were found it would be slight. Williams and I decided, therefore, to test the immunologic reactions of isolations from more than 100 cases. We also tested great numbers of isolations from a few cases. Miss Valentine and Miss Cooper carried out the tests with the utmost care. They used, for every strain, direct and absorption methods.

DIFFERENT STRAINS

It was found that from the same case either all or the great majority of isolations were identical in their reactions, but that the majority of the isolations from different cases differed from each other either completely or essentially. The results seemed to show that influenza bacilli, like pneumococci, have gradually through the years altered on the mucous membranes of healthy carriers into many strains which, while having many essential characteristics in common, are still different in their susceptibility to specific immune substances and perhaps in other reactions.

In order to test the stability of the strains, we passed several strains through a series of animals, and others were grown for many generations on different mediums, but without causing any appreciable change. An interesting observation was made during this work that when a plate culture is made from material containing several strains, apparently pure colonies will not infrequently yield two different strains. The resultant mixed culture will agglutinate with each of the two serums. Even further plating may fail to separate them. If thoroughly shaken before plating, pure cultures of each strain can usually be isolated from the majority of the colonies.

An important point was whether the infecting strain could be depended on to produce the major part of the organisms in a case. If it did, isolations from the plates made from nasopharyngeal cultures could be considered as belonging to the infecting strain.

Some of our laboratory findings are instructive: One of the workers developed an acute bronchitis. Cultures revealed abundant influenza bacilli. Fifty fishings of colonies from the plates were found on testing to give forty-nine identical organisms and one that belonged to a different strain. Another bacteriologist, by accident, received an infection from a freshly isolated culture. About thirty colonies were fished from the plate cultures, and all proved to have identical characteristics. Other tests gave the same results.

PRIMARY AND SECONDARY INVADERS

It seems right, from the results mentioned above, to assume that the infecting strain is in great excess during an infection and that in nearly every case the colony tested will represent the infecting strain and that the proof that the patients are infected by different strains indicates almost certainly that bacilli were present before and that some other virus created conditions permitting the latent bacilli to attack the tissues.

It is perhaps well to state that not only did Miss Valentine and Miss Cooper subject themselves to the most careful controls, but that they also tested the strains with marks of identification that left them in ignorance of the origin of the cultures.

There was no question in our minds of the essential accuracy of the results.

These results appear to us to throw the influenza bacilli in the cases studied as clearly into the class of secondary invaders.

We believe that the other micro-organisms, such as certain streptococci and pneumococci which are under suspicion in different localities will be found after subjection to similar severe tests not to possess the necessary identity of characteristics to allow them to remain under serious consideration as the primary agent in this epidemic, but rather like the influenza bacillus, to be reckoned among the most important of the secondary invaders.

Our final conclusion is, therefore, that the micro-organism causing this epidemic has not yet been identified.

THE SYMPTOMATOLOGY AND COMPLICATIONS OF INFLUENZA*

LEWIS A. CONNER, M.D.

NEW YORK

To present a paper on this subject at a time when the periodicals are filled with articles of similar title, and to an audience, almost, every member of which has had an all too large personal experience with the subject, requires a word of explanation, if not of apology. To be accurate, the title should read "The Symptomatology and Complications of Influenza as Seen in the Army in This Country." No attempt is made to record the manifestations of this disease as they appear in children, in women, or in persons of advanced years; nor as observed in our own, or in other, armies in Europe. Moreover, the statements to be made relate solely to the great epidemic which swept over the country in the autumn of last year. It is interesting to note, however, that in the late winter and the spring of 1918, epidemics of what was regarded locally as influenza appeared in several of the army camps and posts. The symptoms bore a close resemblance to those of the great epidemic six months later, but these local epidemics were distinguished from the latter by the mildness of the symptoms and the rarity of serious complications.

The data on which this paper is based were furnished by reports to the Surgeon-General from seventy-two base and general hospitals scattered throughout the entire country.

In this large number of reports, two features stand out with great distinctness: first, the singularly uniform and clear-cut clinical picture presented by the cases of uncomplicated influenza in the same camp; and, second, the striking agreement by observers in the various hospitals throughout the country as to the characteristic symptoms of the disease. From these reports there can be no possible doubt that, among the soldiers at least, the disease in its march across the country, from the Atlantic to the Pacific, preserved a remarkable uniformity in its clinical picture.

Of forty-seven reports on this subject, thirty-six gave the period of incubation as three days or less. In half of this number it was given as two days or less. In several reports it was stated as being usually not more than twenty-four hours. On the other hand, in several instances, the interval was placed at from three to seven days and, in one instance, at from seven to ten days. In one camp, in the case of five men with whom

the interval between exposure and the onset could be accurately determined, the period in each instance was forty-eight hours. It seems safe to conclude, therefore, that the incubation period is, in general, very short and that the most frequent interval is about forty-eight hours.

In what follows it should be clearly understood that, for the moment, only the symptoms observed in simple, or uncomplicated, influenza are being considered.

ONSET

There is practical unanimity in the assertion that the onset is abrupt in the great majority of cases. Most reports give the percentage of abrupt onsets to the whole number as from 80 to 90. The initial symptoms were surprisingly constant and uniform, being chilliness, prostration, fever, headache, backache, and pains in the limbs. Somewhat less frequent initial symptoms were an irritating, dry cough and sore throat. To these symptoms must be added a characteristic mental state and a peculiar facies which will be described later.

SYMPTOMS

Prostration.—This was one of the earliest, as well as one of the most constant, symptoms. Frequently extreme, it varied much in its severity and in its duration; but it was characteristic of many cases that the muscular weakness persisted long after the temperature had become normal and all the other symptoms had disappeared.

Respiratory Symptoms.—There is general agreement that cough was present at some time in almost all cases, even in most of those classed as uncomplicated. During the early part of the illness it was usually of a hard, dry, racking character, with little or no expectoration, and was commonly associated with a feeling of retrosternal soreness or pain. During the later days of the attack it usually became looser and was accompanied by sputum and by the physical signs of tracheitis or bronchitis. The sputum varied much in character and in quantity. At first scanty, tenacious and mucous, it later became more profuse and mucopurulent. Occasionally, even in uncomplicated cases, it showed streaks of blood and, rarely, blood in considerable quantities.

The frequency of hoarseness as a symptom seemed to vary much. Often the husky voice appeared to depend on the dry, congested state of the pharynx, and on the great prostration, rather than on an actual laryngitis.

Coryza was, in most reports, classed as a frequent manifestation. It was by no means constant, however, and, in some hospitals, seems to have been of infrequent occurrence.

Epistaxis was a striking symptom in many patients. It was present in approximately one fourth of the cases, and sometimes was so severe and persistent as to cause very serious concern. Some observers noted that it seemed to be more frequent in those patients who, later, showed evidences of pneumonia, than in those who did not.

The respiratory rate in simple influenza showed very little disturbance. In relation to the height of the temperature it was notably low. A steady rise in the breathing rate was one of the most trustworthy indications of the existence of a complicating pneumonia. The physical signs of the chest were usually quite normal during the first day or two of the illness, and, indeed, not infrequently throughout the attack. Often,

* Read before the joint meeting of the Section on Pharmacology and Therapeutics, the Section on Pathology and Physiology, and the Section on Preventive Medicine and Public Health, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

however, silant and sonorous sounds, with, or without, scattered, coarse râles, were audible in the latter part of the illness.

Circulatory Symptoms.—There is abundant testimony to the effect that one of the characteristic and striking features of influenza is a slow pulse. Even with a high temperature the rate was usually only 80 or 90 per minute. Rarely was it more than 100, and not infrequently it was as low as 70. A tendency to diastolic was common. With the fall of temperature at the beginning of convalescence, the pulse sometimes dropped to 50 per minute. Disturbances of rhythm were rare. Changes in the heart's size, or evidences of serious disturbance of the cardiac function were almost unknown. In a certain proportion of the convalescents, however, persistent tachycardia occurred.

The arterial blood pressure seemed to show no characteristic or significant change. A tendency toward unusually low diastolic pressure is noted in one or two reports.

The blood showed a striking and constant feature in the small number of the white blood cells. The count rarely exceeded 10,000 per cubic millimeter, and was usually less than 6,000. A leukopenia of from 2,000 to 3,000 was by no means uncommon. Even in the presence of a complicating pneumonia, the leukopenia tended to persist. The reduction was mainly at the expense of the polymorphonuclear cells.

Symptoms Referable to the Nervous System.—Of these, pain was much the most conspicuous. Headache, usually frontal, constituted one of the earliest and most constant of symptoms, and was generally associated with severe backache and aching pain in the extremities. As has been said, dull, retrosternal pain was frequently complained of. Abdominal pain was of rare occurrence. Occasionally, but rarely, there was marked general hyperesthesia of the skin and underlying tissues.

Great apathy, mental dulness and somnolence marked the early stage of the attack in most cases, and with these symptoms there were usually also great depression of spirits and loss of "nerve." In a few of the reports, insomnia is described as of frequent occurrence.

In uncomplicated influenza, delirium was rarely seen. The syndrome of meningismus also was very rare. One point in which this epidemic seemed to differ from that of 1889-1890 was in the absence of severe neuralgic pain, either as a symptom or as a sequel.

Gastro-Intestinal Symptoms.—In general, gastro-intestinal symptoms played a very inconspicuous rôle in the clinical picture. In only one out of seventy-two reports were cases with predominant gastro-intestinal symptoms classed as frequent. In almost all the others such cases were described as rare. Nausea was not uncommon, and vomiting occurred occasionally, but was rarely severe or persistent. Troublesome diarrhea was conspicuously infrequent. Abdominal tenderness was sometimes encountered, but seemed usually to be either a part of a general hyperesthesia or related to inflammation in the chest which involved the diaphragmatic pleura. Very rarely it was caused by a complicating local or general peritonitis. A recognizable swelling of the liver or spleen seemed to be no part of the usual clinical picture.

Sore throat was frequently complained of, and was due to congestion and inflammation of the pharynx

and soft palate rather than to tonsillitis. The uvula commonly was swollen, red and edematous at its tip.

Cutaneous Manifestations.—Perhaps no group of symptoms was more varied and interesting than that referable to the skin. One of the characteristic and striking initial symptoms was the hot, turgid, flushed appearance of the face which, with the swollen and injected conjunctivæ, suggested to many observers the facies of measles without the characteristic eruption. The flushing often extended beyond the face and neck to the chest and trunk generally. Sometimes it assumed the character of a distinct, erythematous rash, which occasionally was so punctate as to bear a close resemblance to that of scarlet fever. This resemblance was sometimes accentuated by the character of the desquamation which followed.

Occasionally, the eruption, instead of being erythematous, was composed of discrete macules scattered over the face and the upper part of the trunk, and showing, at times, a tendency to appear in successive crops.

Herpes of the face and lips was seen in perhaps 10 per cent. of the cases. In spite of the frequency of epistaxis and the occasional tendency to free bleeding from the bronchi, hemorrhagic skin eruptions, either as petechiæ or as ecchymotic spots, were extremely rare. Sweating was very common, even in cases in which it could not be ascribed to the use of diaphoretic drugs. Itching of the skin was not a symptom. Jaundice in simple influenza was very rare.

The Organs of Special Sense.—Injection of the conjunctivæ was one of the most constant of the early symptoms, and, with the flushed face, the crimson or slightly cyanotic lips, and the dull, apathetic expression, made up a facies which, by general agreement, is characteristic of and peculiar to influenza.

Another common symptom was pain and stiffness on movement of the eyeballs. Photophobia, while occasionally very marked, was a much less frequent symptom. Loss of power of accommodation was noted in a few cases.

Earache is classed, in most reports, as an infrequent or rare symptom in the uncomplicated cases. Disturbances of hearing were extremely rare, as were also disturbances of the sense of taste and of smell.

Urinary Symptoms.—Among the outstanding clinical features of influenza must, I think, be included the surprising immunity of the kidneys and, indeed, of the whole urinary tract, from damage by the virus of that disease. The testimony is universal that serious injury to the kidneys was almost unknown.

While traces of albumin were not infrequently found in the urine during the febrile period, considerable amounts of albumin were extremely rare, as were also casts in significant number, hematuria and evidences of disturbed renal function.

Inflammation of the pelvis, of the kidneys and of the bladder also were rarely seen.

CONVALESCENCE

The rapidity with which, in cases of uncomplicated influenza, complete recovery was established, varied greatly. In a considerable proportion of cases a very few days were all that were required. In a majority of the cases, however, complete recovery was more gradual, and, in not a few cases, convalescence occupied a period of several, or even of many, weeks. In these cases the chief symptoms during this time were

muscular weakness and lassitude, mental depression and persistently rapid heart action.

COMPLICATIONS

In considering the complications of influenza, it must be admitted that it is sometimes difficult to draw a sharp line between conditions which should be regarded as a part of uncomplicated influenza and such as should properly be looked on as definite complications. The distinction must necessarily be a somewhat arbitrary one. This is not the place for a discussion as to the propriety of regarding pneumonia as an intrinsic part of influenza. In spite of the fact that in certain cases the pulmonary inflammation seems to be present from the very onset of the illness, there are, it is believed, sound theoretical and practical reasons for following the usual custom of placing pneumonia in the category of complications.

Pneumonia.—In the Army reports, the incidence of pneumonia among cases of influenza varies from 8 to 23 per cent. These variations are to be explained in part, but only in part, by the difficulties in many instances attending the diagnosis of pneumonia, and by the fact that in different hospitals widely different criteria have been used as the basis for the diagnosis.

In most hospitals the percentage of cases of influenza complicated by pneumonia has been between 10 and 15.

From the extraordinary variety of the pulmonary lesions found in patients dying of influenzal pneumonia, as well as from the multiplicity of types of the infecting micro-organisms, it is not surprising that the clinical picture should be exceedingly varied and complex. To cover in detail all of these clinical variations is far beyond the scope of this review. Only the more important and salient features can be touched on. It is necessary, however, to emphasize the close relation which exists between the purely clinical aspects of the disease and the nature of the dominating organism in the lung. This relation seems to be especially important in the case of *Streptococcus hemolyticus* and of *Staphylococcus aureus*.

Onset: With respect to its mode of onset, influenzal pneumonia may be divided into three groups of cases: first, those in which the symptoms and signs of pneumonia develop almost imperceptibly in the course of the active, febrile stage of the influenza, the patient gradually becoming sicker at a time when convalescence might naturally be expected; second, those in which the pneumonia supervenes after the patient has definitely entered the stage of convalescence, and usually after the temperature has been normal for several days; third, those cases which, from the very beginning of the illness, bear the aspects of a pneumonia. In such cases the onset of the attack is apt to be marked by a distinct rigor. Except in this last class of cases a chill is infrequent as one of the initial symptoms of pneumonia. Usually the onset is marked by a more or less gradual rise in temperature and by an increase in all of the respiratory symptoms.

Outstanding Clinical Features: The following may be classed as the outstanding clinical features of influenzal pneumonia as seen in the Army as compared with primary pneumonia of the familiar type:

The temperature usually showed a less abrupt rise, a somewhat lower range of level, a greater tendency to the remittent type, and, in cases in which the patients recovered, a less critical fall to normal. The pulse rate tended to maintain a somewhat lower level than is

customary in pneumonia, and in certain cases was conspicuously slow. In unfavorable cases, however, the rate often became very high.

Much the same may be said of the respiratory rate. In many cases, during the early days of the pneumonia, the breathing rate was hardly greater than normal and, even in the presence of deep cyanosis, the breathing was sometimes surprisingly slow and quiet. This, of course, does not apply to all cases. In some, especially in the fulminant cases with early pulmonary edema, the respiratory distress was a marked feature, and the breathing was often very rapid as well as labored.

The importance of cough as a symptom varied greatly. In many cases it was distressing enough, but in general it may be said that a much larger proportion of influenzal pneumonias is characterized by almost complete absence of cough than is the case with primary pneumonia. The pneumonia wards in the great Army hospitals during the epidemic were often strangely quiet.

The sputum showed extraordinary variations, both in character and in quantity. Usually it was much more profuse and less viscid than in primary pneumonia, and of mucopurulent or of frankly purulent character. Blood was usually present at some time, but less often had the characteristic rusty or brick dust appearance than that of unchanged blood. In many cases, considerable amounts of blood were raised. In the fulminant cases, with early and intense edema, great quantities of pinkish, frothy, watery fluid were poured from the bronchi. In not a few cases there was complete absence of sputum.

The characteristic sharp, stabbing pain of pneumonia was conspicuous by its rarity. A majority of the patients had little or no pain of any sort. Often the pain was referred to the sternum and had a "gnawing" or "burning" character.

The physical signs of the chest were distinguished by their late appearance, their indistinctness, their wide distribution, their slow disappearance and the infrequency of the signs of frank consolidation. The signs were almost always bilateral. They usually appeared first over the lower lobes posteriorly in the form of small areas of fine, crackling râles, impaired resonance, and great diminution or suppression of the vesicular murmur.

Cyanosis.—One of the distinctive features of the pneumonia complicating influenza was the prevalence of cyanosis of a degree which is quite exceptional in the familiar primary type of the disease. When associated, as it often was, with marked pallor, it gave a peculiar dark gray tone to the skin which early came to be recognized as of sinister import.

Chickering¹ associates a special type of cyanosis of "cherry-red indigo-blue color" with those cases in which *Staphylococcus aureus* is the dominant organism in the lungs.

A characteristic feature of the cyanosis, in many cases, was the entire absence of subjective distress and air hunger. Stupor and delirium were common symptoms in severe cases. The delirium was of two types: the active, violent form which required unceasing watchfulness, and the quiet, muttering type which was accompanied by the other usual signs of the "typhoid" state.

¹ Chickering, H. T., and Park, J. H.: *Staphylococcus Aureus Pneumonia*, J. A. M. A. 72: 617 (March 1) 1919.

While leukopenia was not quite so universal as in simple influenza, it nevertheless was present throughout the pneumonia in the majority of cases, and often was very pronounced. Counts of 3,000 or less were not so very infrequent.

Duration: The average length of life in fatal cases, from the time of recognition of the pneumonia, may be stated as between four and five days, and from the onset of the influenza, as from seven to ten days. Among the patients who recover, the average length of the febrile period is somewhat longer.

Fulminant cases: Special reference should be made to a remarkable clinical type which, in a few camps, notably at Camp Sherman, was sufficiently common to form an outstanding feature of the epidemic. The patients, even on admission to the hospital, showed extreme cyanosis, high fever and intense air hunger, and died in from twenty-four to forty-eight hours. The chest was filled with coarse, bubbling râles, and pinkish, frothy serous fluid often poured from the mouth and nostrils. The postmortem findings in the lungs were those of intense congestion and edema, without actual pneumonia. Friedlander² compares the clinical picture to that seen after severe exposure to chlorine gas.

Other Respiratory Complications.—Severe acute laryngitis, sometimes with ulceration, was a not uncommon complication in the pneumonia cases.

A certain proportion of influenza patients, instead of having only a mild bronchitis, develop a severe, purulent form which may last for weeks or months and may be associated with multiple, small bronchiectases.

Pulmonary Abscess.—The suppurative processes which frequently complicate the pneumonia of influenza seem to result chiefly, if not entirely, from the action of *Streptococcus hemolyticus* and *Staphylococcus aureus*. Such abscesses are usually small and multiple and are much more frequently found at necropsy than recognized during life. Solitary, large abscesses are rare.

Pleurisy and Empyema.—In general, in influenzal pneumonia, all forms of pleurisy were noticeably rare in cases of pneumococcal origin; and, except in hospitals in which streptococcus cases were numerous, pleural complications were much less frequent than we are wont to expect in primary pneumonia.

In the streptococcus cases, however, the pleura is extremely prone to infection, and empyema, either free or sacculated, was common. An important type clinically was the small, interlobar empyema, so difficult often to recognize, and so frequently mistaken for unresolved pneumonia. The incidence of empyema among the pneumonia cases probably did not average more than 5 per cent.

Subcutaneous Emphysema.—A remarkable but rare complication, a few examples of which were encountered at almost every camp, was extensive, subcutaneous emphysema. It was usually seen in cases of severe pneumonia, and appeared first either in the episternal notch or above the clavicles, extending thence rapidly to the neck, face, scalp, chest, arms and trunk and, sometimes, to the scrotum. The prognosis in such cases seemed to depend rather on the severity of the pneumonia than on the existence of the emphysema. Such emphysema has been proved not to be due to gas bacillus infection. The mechanism of its production

is discussed by Berkley and Coffen.³ In most cases, certainly, the air finds its way to the subcutaneous tissue by the rupture of air vesicles and by passing thence along the vessel sheaths to the hilum of the lung and to the superior mediastinum. In both of two cases with this complication coming to necropsy at the base hospital at Camp Jackson, the lungs showed *Staphylococcus aureus* infection, with multiple miliary abscesses, most numerous just beneath the pleura.

In a few instances the emphysema has been associated with a pneumothorax.

Serious heart complications were conspicuously rare, even in the pneumonia cases. The severer forms of arrhythmia, such as auricular fibrillation and heart block, were occasionally observed, and rarely a pericarditis was found, sometimes during life but usually only at the necropsy table.

The persistent tachycardia, so frequently seen during convalescence from influenza, seems to be a purely functional disorder, belonging to the category of the so-called irritable heart of soldiers, and related to the general asthenic state rather than to any actual heart damage. There is no reason whatever to believe that it indicates a myocarditis or myocardial degeneration. Its tendency is wholly in the direction of complete, if gradual, recovery. This tendency may be largely nullified, however, by the unwise policy, on the part of the physician, of permitting the patient to believe he has some serious heart disorder which demands the strict avoidance of exercise and exertion.

Thrombophlebitis.—This was an infrequent, but important, complication. It usually involved the leg veins and was associated, in an unusually large proportion of the cases, with fatal pulmonary embolism.

A very few instances of thrombosis of the arteries of the leg, with gangrene, are recorded.

Complications Referable to the Nervous System.—Of these, the most important, meningitis, seems to have occurred only in the cases complicated by pneumonia, and even in these cases was comparatively rare, although a considerable number of instances have been recorded. At Camp Jackson, among eighteen cases of meningitis complicating influenza, thirteen were caused by the meningococcus, four by the pneumococcus and one by the staphylococcus.

The types of delirium seen among the pneumonia cases have been referred to. Mental depression, in the frequent cases of slow and tedious convalescence, was often pronounced, and sometimes amounted to a true psychosis with suicidal tendencies. In general, however, the psychoses belong rather to the sequelae than to the complications of influenza and, as such, are beyond the scope of this paper. The relation to influenza of such organic nervous diseases as lethargic encephalitis and epidemic poliomyelitis is still obscure and uncertain.

Complications referable to the gastro-intestinal tract are few and infrequent. Inflammation of the parotid gland was occasionally seen among the severe pneumonias. Jaundice, even in the pneumonia cases, was very infrequent. Marked tympanites was a frequent and dreaded symptom among the severe pneumonias.

A few instances of peritonitis, generally of pneumococcal origin, have been reported. Most of these were localized in the diaphragmatic region or the upper

² Friedlander, Alfred; McGee, C. P.; Shub, J. E., and Wheeler, G. W. The Epidemic of Influenza at Camp Sherman, Ohio, J. A. M. A. 71:1352 (Nov. 10) 1918.

³ Berkley, H. K., and Coffen, T. H.: Generalized Interstitial Emphysema and Spontaneous Pneumothorax, J. A. M. A. 72:535 (Feb. 29) 1919.

abdomen. In a very few instances the peritonitis was general.

Arthritis.—As a complication, arthritis was rare. Occasionally a pneumococcal arthritis was seen in cases complicated by pneumonia.

Disturbances of the kidneys, as has been said, formed no part of the clinical picture of simple influenza. In a few of the cases complicated by pneumonia, evidences of nephritis appeared; but such cases were rare and the nephritis usually mild in type.

Inflammation of the Middle Ear.—This is classed, in most reports, as an infrequent complication. Figures are available from one base hospital (Camp Hancock) in which systematic and regular examinations of the ears of all influenza patients were carried out. Among 7,800 cases of influenza, an otitis media sufficiently pronounced to call for incision of the drum was found 300 times, or in about 4 per cent. of the cases. Among these 300 cases of otitis, a mastoiditis of sufficient severity to demand operation occurred only four times. There is much testimony to the effect that, in most camps, mastoiditis was a rare complication of influenza.

Inflammation of the Accessory Sinuses.—This was, clinically speaking, a very infrequent occurrence. Only rarely were frank examples of frontal or maxillary sinusitis encountered; but the postmortem findings in patients dying of pneumonia told a very different story. In these fatal cases, purulent inflammation of the sinuses was very commonly found. Among fifty-five necropsies at the base hospital at Fort Riley,¹ the sphenoidal sinus was shown to be involved in 68 per cent., the ethmoidal sinus in 31, and the mastoid cells in 41. The frontal sinus was affected in only two cases.

COMPARISON OF RECENT EPIDEMIC WITH THAT OF 1889-1890

For one who, as a hospital intern, had a personal experience with the influenza epidemic of 1889-1890, it is interesting to review the clinical features of that epidemic and to compare them, one by one, with those of the recent pestilence. After such a review no one can, I think, have the least doubt as to the identity of the two epidemics. Not only is there a striking similarity in the modes of onset and in the symptoms of the disease proper, but, in the tendency to special complications, and in particular to pneumonia of an unusual type, the resemblance is extremely close. All the well known diagnostic features of the present epidemic find their counterparts among those of the earlier one; the abrupt onset, the prostration, the pains, the injected conjunctivae and painful eyes, the characteristic skin rashes, the prevalence of respiratory symptoms—all these are features common to both epidemics.

Certain differences, chiefly of degree, can be noticed, however. The virulence of the recent epidemic was unquestionably greater. A larger proportion of the population seems to have been attacked; the incidence of pneumonia has been greater, and its mortality has also been somewhat greater, apparently.

Examples of the so-called cerebral and gastro-intestinal types of influenza, concerning which much was said and written in the earlier epidemic, have been so rare in the present one as to raise a question as to the propriety of such a classification. In the present epidemic there has been, for all practical purposes, only a single type—the respiratory.

11 East Forty-Eighth Street.

THE MAXILLOFACIAL SERVICE OF THE AMERICAN ARMY IN THE WAR *

V. P. BLAIR, M.D.

Lieutenant-Colonel, M. C., U. S. Army; Senior Consultant, Maxillofacial Service, A. E. F.; Consultant for This Service in This Country

ST. LOUIS

Among the many special problems listed on the preparation program of the Surgeon-General of the Army was the care of injuries of the face and jaws. These had been a particularly trying problem in the Allied armies in the earlier part of the war. In July, 1917, a section of the Division of Surgery of the Head was organized to take over this duty. The motif of preparation was the conviction that the earlier proper treatment could be instituted and continuously carried out, to a proportionate extent would conservation displace reconstruction. To make this practicable would require: first, a sufficiently large personnel to be available at every advanced and at all intermediate and base hospitals; second, a definite general plan of treatment which, instituted in the advanced hospitals, would be carried out without radical change in each of the hospitals to which the wounded would be subsequently evacuated, and thirdly, and not unimportant, suitable equipment.

The proper treatment of maxillofacial injuries rests on the same surgical principles as that of wounds in any other part of the body; but because the proper splinting of a fractured jaw requires dental splints, or splints with dental attachment, and because few surgeons have familiarized themselves with the physiology and the special pathology of the oral structures, to do the work efficiently requires, as a rule, the cooperation of a surgeon with a dental surgeon who has made a special study of the subject.

We had available in this country a large number of dental surgeons who had made this special study, and of surgeons fitted for this cooperation.

EARLY PREPARATION

The Surgeon-General, with the generous and wholehearted cooperation of both the medical and dental professions, and especially of the institutions to be named, established special short courses in the Northwestern University Dental School; in the Evans Dental Institute, University of Pennsylvania, and in Washington University; but the selection of teachers was not confined to the faculties of these particular schools. A large number of surgeons and dentists were sent to take the courses, not with the idea that they could be created into specialists, but that the dentists and surgeons could be shown the plan of cooperation, while splint making, the more likely problems, and the anatomy of the parts were being reviewed. Not the least important of the things accomplished by these schools was the data obtained as to the qualifications of officers for the work, which requires also the cooperation of the ophthalmologist and otorhinologist; and the close association of the latter sections with the maxillofacial in the Division of Surgery of the Head simplified the arrangement for this cooperation, which has been harmoniously carried out ever since.

* Stone, W. J., and Swift, G. W.: Influenza and Influenzal Pneumonia at Fort Riley, Kansas. J. A. M. A. 72: 487 (Feb. 15) 1919.

* Read before the Section on Surgery, General and Abdominal, at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

In the matter of equipment, everything asked for was allowed by the Surgeon-General and assembled into sets adapted to advanced and base hospitals.

FRENCH AND BRITISH COOPERATION

In April, 1918, the preliminary work in this country having been carried as far as practicable, the Surgeon-General sent a unit of about twenty surgeons and twenty dental surgeons to the chief surgeon of the American Expeditionary Forces with the request that they be given the opportunity to observe the method in practice for caring for face and jaw injuries in the hospitals of our allies, and through the courtesy of the authorities they were distributed among several British and French hospitals especially devoted to this work, namely, the various Paris hospitals, Queen's Hospital at Sidcup, King George Hospital, England, and British General Hospital No. 20 at Boulogne. Later, as their services were required in our own hospitals, they were gradually withdrawn from these stations. It would be very ungracious if I did not pause in this hurried review to acknowledge the debt we owe to the British and French authorities for the help they gave us in this manner, and I mention, among others, especially Collyer, Gilles, Cole and their staffs; Lemaître, Pont, the late Moristan, Villain and Kazanjian, who did everything they could to make their experiences available to us.

ORGANIZATION OF OPERATIONS IN FRANCE

Shortly after we arrived in France, a senior consultant for maxillofacial surgery for the American Expeditionary Forces was appointed, and a policy for the care of these cases was outlined, which differed a little from the plan contemplated by the Surgeon-General. Information as to the general plan for evacuation and treatment of these patients was sent out. France was divided into seven areas, to each of which a local or area consultant for maxillofacial surgery was appointed. In each American hospital center the cases were concentrated as far as practicable in one hospital, where they were attended by a local consultant for the center, in cooperation with specially selected dental surgeons. In each area, comprising several hospital centers, the area consultant, while he was free to travel throughout his area, was attached to a certain hospital to which he could request to have evacuated any patient who could best be treated at his own hospital, or to Hospital No. 115 at Vichy. The latter had been especially designated and equipped to care for face and head injuries.

LACK OF SURGEONS AND EQUIPMENT

The atmosphere of war, in spite of intense concentration, is one of distraction. All plans of specialization are more or less ideal, and it takes time to put any subordinate plan into operation, especially if it is far-reaching in its application. Each hospital organized in the Surgeon-General's Office had attached to it a surgeon and a dental surgeon designated for this work; but in the earlier part of the severe fighting, all specialization was overshadowed by more vital problems. It is no secret that, owing to the lack of transportation, we were short of surgeons and dental surgeons in the American Expeditionary Forces, and that at Chateau Thierry most of the surgical consultants were ordered to form general operating teams, and they stood twelve hour shifts at the table at any hospital where they could find space; while the dental surgeons were often giving

anesthetics, carrying the stretchers or giving first aid treatment. I have seen a hospital with an operating room capacity of 360 cases per twenty-four hours, at 2 o'clock in the afternoon, in all the confusion of raising the tents, and which, before seven the next morning had received 750 severely wounded—with the stream unaltered; and I know of instances of even greater congestion. At one rail head, two consultants formed a team and carried stretchers for nearly a day.

The foregoing instances are mentioned to illustrate just one of the reasons why it took time to establish these special services.

I believe our service abroad had some success in its work. In my own mind I am very enthusiastic about its accomplishments. When all of the special records of these cases are received from abroad, we shall have definite figures to judge from. Until then, its accomplishments can be measured only by inference. After August 20, there was a breathing spell, during which this service really got on its feet; and from the Battle of the Argonne, September 25, it was on the job and delivering the goods at all stations, if I may be allowed to use this expression. It was a bit of a handicap that little of our special equipment ever became available; but shells and food take precedence over other things. This worried the dental surgeons, who were not backward in worrying the consultant, and the consultant worried every one.

During the St. Mihiel drive, a dental surgeon of a mobile hospital telephoned the local consultant of the advanced area, asking what he could use to take care of the jaw injuries that were accumulating. The consultant replied, "Use your wits," and slammed down the telephone. He had been asked this question once too often. To the credit of our dental surgeons, they used their wits, and by piecing out our own supplies with what the chief dental surgeon could obtain from the French; by beating two franc pieces into splints; by robbing the shell-cut telephone wires, and by cutting meat tins into splints, from the beginning of the Argonne there were few patients who reached the base hospitals unsplinted.

NUMBER AND RECORDS OF CASES

We have at present no definite figures as to the total number of these cases. Taking the statistics for the Union forces in the Civil War, the Prussian forces for the War of 1870-1871, and the British forces for the present war up to Christmas, 1917, as a basis for calculation, they should average at least 1 per cent. of all wounds, which, according to the last report of wounded May 31, 1919, would give a total of more than 2,371 cases.

There have been evacuated to this country to date about 600 patients, and practically no more remain abroad. Of these 600, 260 have been discharged, and eighty-five are ready to be discharged. For the 339 patients now in hospitals, making liberal estimates of the time necessary for total recovery, there are ninety-two who will require two months; eighty-two, four months; fifty, six months; eleven, eight months; seven, twelve months, and one, eighteen months before they can be discharged as well; but it is estimated that the time that will necessarily be spent in the hospital will average from two weeks to ninety days for the foregoing cases. In my recent inspection of four centers I did not see one case in which there was a free discharge of pus; in fact, any pus at all in these cases is very rare.

In this country, these cases have been concentrated in four hospitals, and an arrangement with the Public Health Service is under way which will assure the continuance of their treatment nearer their homes of men who wish their discharge.

In the general planning, the matter of records was included. Abroad, every maxillofacial case was recorded in some detail on a special form designed for that purpose, and these are to be returned to this country, to be correlated with the records here. At certain centers abroad, photographs, casts and wax models were made of the earlier conditions, and tracings of the roentgenograms. At each of the four centers in this country there is attached to this service an artist, a sculptor, a photographer and a stenographer, and an officer is assigned to supervise and assemble the records. The Surgeon-General has sent out instructions as to the general plan of these records, and has ordered that on completion of the work all should be sent to Washington to be assembled with the records from abroad, for a permanent exhibit in the Army Medical School Museum. Part of this record is on exhibit in the Exhibition Hall here.

MASKS

The matter of making masks to camouflage these face injuries was investigated extensively by the Surgeon-General, and a personnel trained for the work. A few were made for our soldiers by the Red Cross in Paris, and several here, by our own staff; but the men will not wear them, preferring plastic reconstruction. There is not, to my knowledge at present, a single mask in use by our soldiers, and Major Gilles of the British service tells me that the soldiers have the same preference. We do, however, use prosthetic reconstructions within the mouth.

IMPORTANCE OF EARLY TREATMENT

In this review of the work it is impossible even to mention technic, but there is one thing that observation has strongly emphasized, and that is that delayed recovery and restoration are on the whole much more dependent on delayed treatment and infection than on primary loss of tissue, and that early treatment will prevent or control infection. It was brought out more strongly than ever before that infection is the chief factor in delayed union or reformation of the jaw bones, not necessarily accompanied by free flowing pus or extensive induration, but a quiet process, often difficult to detect, usually kept up by want of proper drainage and the presence of a foreign body, most likely an exposed tooth root or a piece of denuded bone. No matter how often the observation is repeated, it is interesting to note with what rapidity bony consolidation frequently follows the removal of a tooth or bone spicula from or near a fracture line that was apparently perfectly clean, but in which union had hung fire for months.

The great majority of cases requiring bone grafting do so not from the primary loss of all bone-forming tissue, but because of one or several of the following reasons: The bone-forming structures are destroyed by infection, which causes scar tissue to replace bone reproduction; or there has been a want of proper early splinting, which in itself predisposes to infection. It is usually a combination of both these factors that is responsible for a total loss of a segment, which is more apt to occur if, at the time of the injury, bone fragments are removed. Instances in which all of the

bone-forming tissues are destroyed by the original injury are the exception. Altogether, about seventy-five cases will require grafting, or have been grafted, for bone loss in the lower jaw. Most of these will be pedicle grafts, which require less time for union and are more certain in result than the free bone graft. It has been the policy throughout to restore the normal occlusions rather than to bridge defects by shortening the body of the jaw.

The last jaw case in which I saw an operation performed in the American Expeditionary Forces was a fair illustration of the working of our plan for conservation. Going into the operating tent of a mobile hospital, I watched a young surgeon whom I did not know and one of our dental surgeons assemble, splint and repair a mandible that was shattered from angle to angle, with the lip, chin and floor of the mouth torn open to the hyoid. When they completed their work, the bony fragments were in their proper position, and the soft parts repaired, all with proper drainage. There was left only a slight defect in the lower lip. Had this treatment been delayed thirty-six hours, the patient would have represented one of those horrible cases of total loss of the chin and body of the mandible which have been so frequently depicted. I never saw the patient again, that is, to recognize him, but with the subsequent treatment we were prepared to give it is probable that the soft tissues healed primarily with bony consolidation within three to six months.

NECESSITY OF DENTAL SURGERY

There are two other cases coming to my earliest observation, between which I have frequently made mental comparison. Before cooperation had been made practicable, April 25, 1918, one of the best operators in the American Expeditionary Forces had treated a case with bad laceration and comminution by ordinary surgical methods, with wiring of the fragments. The patient was evacuated and subsequently treated as though his were a general surgical case. Within a short period there entered the service of the same surgeon a rather similar case, which was treated by him and the dental surgeon jointly. I encountered the second patient a month later at a base hospital. The soft tissues had healed with linear scars, the jaw fragments were firmly splinted and in good position, and there was no pus. Six months later I again found the first patient; he was profoundly septic, with fragments of dead bone protruding from the cheek wounds, and there was great deformity. He still will require a bone graft on each side of the body of the lower jaw, and has no lower teeth by which to fix the fragments. "One swallow does not make the summer," but one case will illustrate the surgical principle.

ABSTRACT OF DISCUSSION

DR. ROBERT H. IVY, Milwaukee: I had the privilege of being associated with Colonel Blair practically from the beginning in the organization of the plastic and oral surgery section in the Surgeon-General's Office, and was later at a center in France where a large number of maxillofacial injuries were treated. Our work consisted largely in getting the wounds out of the infected stage so that they would be in proper condition for bone and plastic operations later. A certain percentage of cases of gunshot fracture of the mandible with loss of substance resulted in nonunion in spite of the best of treatment in the way of fixation and removal of sources of infection. At the Walter Reed General Hospital we are employing two methods of grafting: (1) Taking the

pedicled bone graft from the mandible itself, as described by Cole. The graft consists of a piece of the lower border removed from the anterior fragment, with a pedicle of muscle and fascia attached to it below for nourishment. This method is suitable for cases of fracture of the body of the mandible, where the angle is not involved, and where the loss of bone does not exceed 4 cm. We have employed it in two cases, obtaining primary union of the operative wound and firm bony union in one case. In the other case, bony union is apparently taking place two and a half months after the operation. (2) Where the angle and ascending ramus of the mandible are involved or where there is great loss of substance, we are employing the osteoperiosteal method of Delageniere. This method, on account of its simplicity and the good results obtained by French surgeons, deserves to be better known in this country than is the case. The fragments having been previously splinted in their proper relations, the ends are exposed by careful dissection and removal of scar tissue. Especial care must be taken not to open into the mouth. If this happens, the operation should be discontinued immediately. A bed is prepared for the grafts by the creation of pockets between the bony ends and the surrounding soft tissues. The material for the grafts is taken from the tibia, and consists of a thin shaving of the outer layers of the bone with the overlying periosteum attached. The osteoperiosteal method has been used by us in eight cases with losses of substance ranging from 2.5 to 10 cm. Primary operative union followed in all cases except one, in which a hematoma occurred, followed by some suppuration and extrusion of small shreds of bone from the graft. Even in this case, encouraged by the experience of Delageniere, we have good reason to believe that union is taking place. It is too early yet to report as to the final outcome in these cases. The splints will not be removed for at least three months.

DR. GEORGE M. DORRANCE, Philadelphia: I do not agree fully with Colonel Blair in regard to suturing these wounds at the front. They should be drained unless one can control the cases and do not have to transport them to the rear. If you are going to transport the men 300 or 400 miles, the wound should be drained. In cases where I sutured the wound and retained the patient, he did well; when I sent the patient back, he did not do as well. Later, when I was in the rear, I saw many cases which had been sutured and the wound later broke down, necessitating operating over again. My feeling is just to suture the wound sufficiently to give adequate drainage. The important thing is to understand skin grafting of the mouth. At Queen's Hospital, Siskup, they developed free skin graft in the mouth with practically no failures. We have not had a single failure at the Cape May hospital. The operation consists of incising through the mucous membrane or scar and producing a cavity one third larger than is required, thus allowing for subsequent contracture. A model of the cavity is made with modeling compound and later attached firmly in position to the teeth, after a thin Thiersch skin graft is placed over it. If the graft rides beyond this area, it does not make any difference. It is held in there by pressure for a varying length of time, on an average of three to five weeks. We have failed with skin grafts on the outside of the body in a certain percentage of cases. In the reconstruction of noses, we have gone back to the Indian method. We have learned to use the new method adding inverted skin to make the lining of the nose; if this cannot be done, use the inside flap turned down by the Indian method. Every flap for the mouth or for the nose must be lined. In performing these plastic operations, do not plan them so that the patient looks beautiful when he comes off the table, because there is always considerable shrinkage. It is better to turn the skin edges out so that they look like protuberances.

DR. JOHN B. ROBERTS, Philadelphia: Those practicing general surgery found that they could not treat infected fractures of the jaw well, especially when there was loss of bone from injury or from secondary infection. Now there are all over this country, thanks to the activity of Surgeon General Gorgas and Col. V. P. Blair, men who do beautiful work in such fractures. One point of which Dr. Blair spoke is that

of using Thiersch epithelial grafts for replacing the mucous membrane in the mouth. That is a great improvement in oral plastic surgery. Those of us who do plastic surgery know that if one takes mucous membrane from the lower lip and sets it in the orbit after enucleation of the eye to enlarge the socket for glass eye, the mucous membrane graft will grow in the eye socket, although the wound is not truly aseptic. To know now that Thiersch skin grafts may be substituted for the mucosa is a great gain.

DR. VILRAY P. BLAIR, St. Louis: Until the special reports are obtained from abroad it will be impossible to say how many of these injuries we had, but we probably had about 2,500. The great majority of these cases occurred after July 15, 1918. We have returned to this country less than 600 men. Of these 280 are already discharged.

URETERAL TRANSPLANTATION IN INOOPERABLE CONDITIONS OF THE BLADDER *

WILLIAM E. LOWER, M.D.

CLEVELAND

Perhaps no class of patients makes a more piteous appeal to the surgeon than those with inoperable new growths in any location. And perhaps saddest of all are those patients with growths of the bladder in which the irritation and pain are constant and intense and a resection cannot be made, because either the entire bladder is involved or the area around the internal sphincter—conditions which preclude the possibility of a resection and restoration of function. In most of these cases the suprapubic drain does not give the desired relief, for it does not prevent the urine from coming through the bladder and flowing over the raw and ulcerated surfaces. Even large doses of opium do not afford much relief. The only possible method by which any relief can be secured is by preventing the stream of urine from passing through the bladder.

This may be accomplished by transplanting the ureters into one or two practical locations—into the loins, or into some portion of the large intestine, preferably the sigmoid or rectum as near the bladder as is possible.

If the ureters are transplanted into the loin, a mechanical contrivance to catch the urine is required; and even the most convenient appliance for this purpose is not, as a rule, satisfactory. On the other hand, if the ureters are transplanted into the large intestine, the patient is subjected to but little annoyance, for the sphincter ani becomes adapted to the new condition, and effectively controls the urine.

Various kinds of technic, etc., have been devised, perhaps the best of which in suitable cases is that of Coffey. The operation is preferably performed in two stages, transplanting one ureter first and then waiting a sufficient time to be sure that the ureter is functioning in its new location, and to allow the sphincter ani to become adapted to the new condition, when the second ureter is transplanted. Preferably the right ureter is transplanted first, as, if adhesions follow, as they often do, the rectum becomes more or less fixed and cannot so readily be drawn into the cut.

In certain cases, at a third operation, the entire bladder may be removed and the patient's comfort be still more increased and life also materially lengthened.

* Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

ened. I have performed this final radical operation in two cases after transplanting the ureters. One of these patients survived for two and one-half years and during most of that time was able to carry on his normal vocation, while previously he was unable to do so because of the great pain and frequent annoying urination. I lost track of the second patient six months after the operation, and have not been able to ascertain how long he survived. In both these instances, the relief was immediate, and the operation was fully justified.

In two other cases, the ureters were transplanted simply for relief, for the growth was so extensive as to preclude the possibility of a more radical operation. In neither of the latter cases did the patient survive for any great length of time, but in each the patient was relieved of his previous annoying symptoms.

The intense relief to the patient from an almost intolerable condition seems to me to indicate that this method should be adopted in those extreme cases which cannot be relieved by any other operation. If these patients present themselves early enough for a complete extirpation of the bladder after the ureters have been transplanted, the life may be much prolonged and occasionally a complete cure is accomplished.

The division of the operation into two stages—or three, if extirpation of the bladder is possible—not only affords an opportunity of noting that the ureters are functioning properly, but also aids in conserving the patient by dividing the trauma of the massive operation.

REPORT OF CASES

I. TRANSPLANTATION OF URETERS WITH EXTIRPATION OF THE BLADDER

CASE 1.—A man, aged 42, consulted me in July, 1916, because of pain in the small of the back, blood in the urine and frequency of urination. There was difficulty in starting urination, and much pain until the clots of blood were passed. Frequency of urination had increased until the patient was obliged to void every twenty or thirty minutes. The patient thought he had lost about 30 pounds since he first felt symptoms of his present illness in the preceding March. A mass could be felt in the region of the bladder. No satisfactory cystoscopic examination could be made.

July 31, an exploratory operation disclosed a large infiltrating, indurated mass which seemed to involve the whole of the bladder and, at one point, extended through the wall. As nearly every point of the bladder appeared to be involved, resections of any part seemed impossible.

August 8 and 22, respectively, the right and the left ureters were transplanted into the rectum.

September 15, the final operation was performed, in which the entire bladder, which was almost filled with an extensive carcinoma involving the internal sphincter, was extirpated. September 30, the patient was discharged from the hospital. He was feeling much better; the pain was relieved, and he had fine control of the anal sphincter. This patient survived for two and one-half years, returned to his work, and was quite comfortable until the growth recurred in the peritoneal cavity and involved the intestine.

CASE 2.—A man, aged 53, was first seen in January, 1917, having been transferred from the Medical Service at Lakeside Hospital, as he was thought to have some prostatic trouble. He complained of much pain in the left kidney region. Cystoscopic examination disclosed a growth of considerable extent occupying the right side of the bladder in the neighborhood of the right ureter and involving the most of the internal sphincter.

February 6 and March 3, respectively, the right and left ureters were transplanted into the sigmoid.

March 27, the final radical operation was performed, the entire bladder being extirpated. The growth was a carcinoma.

April 8, the patient was discharged. All drainage tubes had been removed; there was a very slight discharge of seropurulent material. Discomfort had almost entirely disappeared and the patient had good control of the anal sphincter.

The patient was last heard from six months after the operation, at which time he was comfortable and in good general condition. How long he survived after that I have not heard.

II. TRANSPLANTATION OF URETERS WITHOUT EXTIRPATION OF THE BLADDER

CASE 3.—A man, aged 50, was first seen in January, 1915, when he gave a history of frequency of urination for thirty years. He stated that ten years previously he had been operated on for an abscess between the rectum and the bladder. Later he had passed gravel, and the frequency had been more marked. At this time and again in November of the same year operations for stone in the bladder were performed.

In March, 1919, the patient returned with the same complaint of frequency, which had become much aggravated during the preceding three or four months.

March 11, an exploratory operation disclosed a hard nodular bladder about the size of an orange. Numerous nodules varying from the size of a pea to half an inch in diameter were found within the bladder wall and on the peritoneum. No further metastases were found, though they undoubtedly existed.

It was obvious that the only aid which could be given the patient must be palliative through the transplantation of the ureters. Thereupon, March 22, and April 3, respectively, the right and left ureters were transplanted into the sigmoid. The patient survived only a short time, but was entirely relieved of the pain while he lived.

CASE 4.—A man, aged 57, seen in October, 1918, first began to suffer from frequency and burning of urination three years before. During this period he received continual medical treatment and was relieved at times.

In July, 1918, blood began to show in the urine. At times the patient suffered from dribbling, but never had complete incontinence. Cystoscopic examination revealed a massive growth in the bladder.

October 3, a suprapubic cystostomy disclosed a large cauliflower fungating tumor mass, growing from the base of the bladder, the limits entirely occupying the bladder capacity. As in our other cases here reported, it was obvious that the best we could do would be to supply what comfort we might to the patient by transplanting the ureters. Therefore, October 11 and 23, respectively, the right and left ureters were transplanted to the sigmoid. The patient lived only two weeks after the second operation, but it supplied the only relief he had had for six months.

In all these cases the kidneys were involved.

CONCLUSION

The transplantation of ureters for inoperable malignant growths of the bladder is not new, but it has not been as common as it seems to me it might be; and in the occasional case, a complete extirpation of the bladder may be done not only with the promise of prolonging life, but with the possibility of an occasional complete cure.

ABSTRACT OF DISCUSSION

DR. B. A. THOMAS, Philadelphia: My experience is limited to a few cases, in some of which the ureter was transplanted into the loin by the process of ureter fistulization. In others a bilateral nephrotomy was done; and in still others the ureters were transplanted into the bowel. It seems to me that we can, perhaps, entirely exclude the utility of ureteral fistulization in the loin. In my own experience every patient died very shortly afterward of pyonephrosis by reason of the poor drainage which seems to be obtained by that method.

Therefore, we have to decide between a bilateral nephrectomy or a bowel implantation. Dr. Lower referred entirely to malignant conditions of the bladder, that is, carcinoma. These patients will not live a long while. In a few weeks, or a few months, or occasionally a year or so, they will die of an ascending renal infection. Bowel implantation is the preferable procedure, so far as the comfort of the patient is concerned. Therefore, I believe it should be selected in all cases of carcinoma of the bladder, where longevity is in doubt anyhow. The patient will be more comfortable. However, in a condition such as multiple papilloma or degeneration of the bladder, we might resort to loin nephrostomy and obtain a better result.

HYPERTENSION IN WOMEN *

DAVID RIESMAN, M.D.

PHILADELPHIA

The habitual use of the blood pressure instrument has brought me a number of surprises, none greater than the frequency with which hypertension occurs in women. The majority of the cases can be classified in a distinct and definite group having the following features in common:

1. The patients are usually stout, overweight and undersize.
2. They have borne many children.
3. They have neither a history nor any stigmata of syphilis.
4. They are over 45 years of age, the greater number falling between 50 and 60 years.
5. They are practically all constipated and some of them suffer from intestinal indigestion.
6. Up to a certain point they show an amazing tolerance to pressures of high degree.
7. In most instances the heart is enlarged, chiefly to the left.
8. The arteries are soft and even the retinal vessels rarely show any involvement.
9. The kidneys, as far as it is possible to determine, are competent.

The absence of gross renal and arterial changes has led writers to speak of such hypertension as essential, a word of little meaning though quite adequate for concealing our ignorance of the cause of the trouble. A similar hypertension is met with in men; but in them it is less frequent and in general less innocent.

When we come to search for causes, the points that stand out prominently are:

1. Multiple gestations. In nearly every case there have been not only two or three, but often five and six children. I have gotten the impression that the worries incident to raising a large family may count for no less than the repeated pregnancies. Ignorance has not elicited a history pointing toward any noteworthy abnormalities either in the pregnancies or in the lying-in periods.
2. Worry. Serious worry is rarely absent; on the one hand, heavy household cares; on the other, special trials and tribulations of the soul.
3. Constipation and intestinal indigestion, especially of the flatulent variety. Just what share to assign to these it is difficult to say. They may play a very important role as possible sources of autointoxication. I have, however, seen hypertension of this type in women in whom there was perfect function of the alimentary canal.

4. The menopause. The hypertension begins in such a high percentage of cases during the menopause that this constitutes an unquestionable etiologic factor. The relationship suggests the thought that this form of hypertension in women is based on some endocrine disturbance, not improbably arising in the ovary. Nearly 50 per cent. of the patients were widows.

Whatever the cause may be, whether it is of endocrine origin or some toxic substance made in the intestines or the slow poisoning from a focus of local infection, the effect is an increased vascular tonicity which gradually leads to an actual thickening of the muscular coat of the vessels.

It is interesting to note the symptoms presented by the patients in the early stages of the disease, the inaugural symptoms, to employ a useful phrase of Moynihan's. They are dizziness, ringing in the ears, dyspnea on effort, anginal pains, palpitation, gaseous distention, and vasomotor disturbances. Though several of these symptoms may be found in the same patient, the disease is often monosymptomatic in the beginning. In a very large proportion of cases the complaints, such as brachial neuritis, sciatica, migraine, have no apparent connection with the hypertension.

The chief physical findings are as follows:

The complexion is usually florid; obesity is practically constant; the area of cardiac and of aortic dulness is increased; a systolic murmur at the aortic area, transmitted upward and into the clavicles, and a ringing second aortic sound are common findings. In the later stages a soft systolic murmur can often be heard at the apex. The temporal arteries may be tortuous, but as a rule they are not conspicuous in women. The peripheral arteries are soft, in striking contrast to the blood pressure. An almost constant finding in patients of this type coming to the office is a slight elevation of temperature, between 99 and 100 F.

The average age of the patients was 54 years. The youngest patient was 43, the oldest, 71. The average systolic pressure was 211; the average diastolic pressure, 105; the average pulse pressure, 106; the highest systolic pressure, 310; the highest diastolic pressure, 160, and the highest pulse pressure, 150.

The highest tension, that of 310, was found in a woman, aged 46. Her sole complaint was dizziness. The year previous she had had a uterine hemorrhage. The physician who brought her to me and I myself were completely taken aback when we found the tension so high. From the woman's complaints we had not been led to expect it.

Another patient had a systolic pressure of 290, normal urine, normal eye grounds, and was well and active. She was able to play golf and had practically no complaint save ringing in the ears.

Of course, the type of hypertension I have described is not the only one met with in women. Chronic nephritis with high pressure is fairly common. It may be set down as a general rule that hypertension in women under 35 is practically always nephritic; it gives a bad prognosis, much worse than any other form of hypertension. In some of the nephritic cases the arteries are soft and impalpable; in others, they are hard, tense and rigid. Strange to say, the latter condition is more frequent in the younger patients.

There is, furthermore, the arteriosclerotic group in which the etiology, symptoms and course do not differ from those of the same disease in men.

* Read before the Section on Practice of Medicine at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

I shall merely mention, without further comment, hypertension in acromegaly and in exophthalmic goiter. I want, however, to say a few words about a closely allied type which I would call non-goitrous thyrotoxic hypertension. This form is of considerable clinical interest; like the one of which I spoke first, it occurs with preponderating frequency in women. The patients are near or past the menopause, are not overfat, sometimes spare, often single. They complain chiefly of palpitation and headache; are emotional, and have a tendency to sweating. The heart is rapid, even to the point of tachycardia; the hands are tremulous. There is often a von Graefe sign, but no exophthalmus and no goiter or other tangible abnormality of the thyroid gland. The systolic pressure ranges from 150 to 210, with a diastolic pressure of from 90 to 120. While there is no positive proof of a thyroid cause, and while the patients are nearly all beyond the age at which hyperthyroidism usually appears, the symptoms nevertheless closely resemble those of a thyrotoxicosis. To be sure, the condition may be pluriglandular in origin. It is apparently not renal or arteriosclerotic. A point of interest and in a sense contributory evidence of thyroid origin is the fact that the iodids do not benefit but rather harm these patients. The thyrotoxic form is more incapacitating than the first variety of which I have spoken.

With regard to prognosis, the first type, the so-called essential hypertension, is in a sense benign; even high pressures are well tolerated for many years, as I have pointed out in earlier papers on this subject.¹ Hence, it is both unwise and unnecessary to alarm these patients. Many have been unduly frightened by being told that they had very high blood pressure. Though the physician, in dealing with them, may well be optimistic, nevertheless, for the patients' sake it is important that he keep them under surveillance on account of the possible catastrophes that lie in wait for them. Three major accidents may happen:

1. Angina pectoris, which is much more frequent in women than is believed, and is especially common in the so-called essential type of hypertension. It is probably due to an extension of aortitis to the coronary arteries.

2. Apoplexy with hemiplegia, which later in the majority of my cases has been left-sided.

3. Decompensation, a late stage of the disease resulting from myocardial exhaustion.

TREATMENT

In this, as in all chronic diseases not definitely infectious in character, our powers of cure are very limited. That being so, the great desideratum is to find means of prevention. To this end we must learn to recognize hypertension in the making and then to remove such removable factors as are concerned in its production. As there may be nothing in the symptomatology in the early stages to attract attention to the circulatory system, there is but one way to discover incipient stages—by routine blood pressure examination and careful determination of the size of the heart. A comparison of records made at intervals would then show us in which patients the pressure was on the upgrade.

In the treatment of the established condition, harm may readily be done by too much interference. Just as we have gotten away from using digitals on the mere

discovery of a murmur when the valvular defect is compensated, so we should not try to lower the blood pressure to any great degree in patients in whom the hypertension is well borne—in whom it is adequately compensated. If the patients know that they have high blood pressure, one may honestly assure them that the dangers of this symptom have been overemphasized.

Regulation of the diet is necessary, more often in the direction of quantity than of quality. I have found this class of patients as a rule to be heavy eaters, and have come to feel that they do better on a restricted diet, especially on one that is largely lactovegetarian. A lamb chop, a little chicken and fresh fish are permissible. Rest, at times a semirest-cure, is desirable in many instances. In some persons, however, graduated exercise, walking and moderate golf playing may safely be advised.

With regard to drugs, I am not in the habit of using them as a matter of routine. The nitrites are not indicated in patients who do not suffer from their hypertension. Though high-gearred, the circulation may be well maintained and vasodilators only serve to upset the equilibrium. The iodids may be used in the essential type of hypertension in small doses over a long period. Lately, I have secured apparently striking results from the use of corpus luteum extracts. The pressures were lowered without any untoward effects, and the subjective symptoms were markedly improved.

Baths and electricity may at times be employed with benefit. When the cases approach the danger line, nothing is so valuable as venesection; when this cannot be done, then leeching from the mastoid process is a very good substitute.

In the thyrotoxic cases, rest is of the greatest importance. Patients of this type should take their breakfast in bed and lie down for an hour or an hour and a half after the noon meal. Tea and coffee should be forbidden. Medicinally, the bromids, at times, with small doses of tincture of veratrum, seem to do good. I may add that in the dizziness of hypertension, tincture of veratrum has often given me very satisfactory results.

The patients of all types of hypertension should be urged not to worry, but the mere injunction "not to worry" carries small weight. It is necessary for the physician to analyze with judgment and with great patience the worry-breeding conditions of the person's life and to convert his patient, if possible, to a more philosophic attitude. By considering all the details of the patient's daily life, one may often point out definite ways of easing the strain.

ABSTRACT OF DISCUSSION

DR. JOSEPH H. PRATT, Boston: Dr. Riesman has done well to emphasize the tolerance with which high blood pressure is borne for a number of years by certain patients, especially by women of middle age and above who exhibit no signs of renal disease. The cases I have studied of high blood pressure with normal renal function may be divided into three groups: 1. Vasomotor neurosis with transitory hypertension. The blood pressure is unusually labile. Slight emotion produces a marked rise. These cases are properly regarded as neurasthenia with vasomotor disturbances. The rise in blood pressure is attributed to vasomotor spasm. Other symptoms due to spasm of the vessels are frequent. 2. Primary permanent hypertension. Elevated blood pressure may be the only sign of disease and there may be no subjective symptoms. Most of the patients at the time they come under observation have enlargement of the heart. 1

1. Riesman, David: *Penit. M. J.* 18: 193-202 (Dec.) 1914; *Am. J. Obst.* 71: 428-133 (March) 1915; *Am. J. M. Sc.* 165: 487-494 (April) 1915.

have seen cases, however, in which there was no evidence of cardiac hypertrophy. Dr. O'Hare, in an unpublished study, has found in hypertonia without renal disease a marked increase in the blood pressure after an injection of epinephrin. This indicates a state of increased tone in the sympathetic nervous system. 3. Localized arteriosclerosis with hypertension. In a large number of cases in this group of localized arteriosclerosis there is evidence of cardiosclerosis. As Dr. Riesman states that in his cases there is an increased area of aortic dullness and a systolic murmur at the base, as well as an enlargement of the heart, it would seem as if they should be placed here. Is the hypertonia primary and the heart hypertrophy secondary, or are the physical signs of involvement of the heart found in the earliest stage? Orthodiagrams and teloradiograms of the heart taken at intervals beginning, if possible, before hypertonia developed and continued over a series of years, would yield information of value. As evidence of emotional instability of the blood pressure is such a marked feature in essential hypertonia, it may be that some of the cases with transitory elevation of blood pressure tend to pass into the second group characterized by a persistent hypertonia. Cases of this type sooner or later exhibit definite signs of localized arteriosclerosis and then belong in the third group. This progression from one group to the next indicates that we may be dealing with different stages of the same disease process which begins with a transitory spasm of the vessels and ends with widespread arteriosclerosis.

DR. LOUIS FAUCERES BISHOP, New York: The whole question of the disposition of these very high blood pressure people is so important that it is well to emphasize some practical points in their care. What shall we do with these people so that they will live for a long time? For the last twelve years I have done nothing but treat blood vessel and heart cases and refer now to pressures of from 210 to 260. I have taken care of many of these persons for long periods of time. And there are certain things that are absolutely the best for them. In the first place, I would select the best remedy of all as outdoor exercise. If you can get these women with very high blood pressures and all the nervous symptoms and everything else that goes with them to take a long walk every day, you have won half the battle in taking care of them, because exercise is the best heart stimulant in the world; it is the best lung stimulant; it is the best kidney stimulant; it is the best antidote to worry. Next to that I would place diet. The most essential element in the treatment of this group is the exclusion of eggs from the diet. Some are sensitive to eggs, but not all of them. But, as a matter of strategy, the exclusion of eggs is essential. If you exclude eggs from the cooking, you exclude a great deal of the protein. In our present economic status eggs are very objectionable, because of poor quality. Of course, excess of meat should be avoided. The third important element is care of the intestinal tract. Most of these people are laxative fiends. They have been taking laxatives all their lives and they suffer from autointoxication which comes to people who abuse laxatives. Castor oil is the best of all. I give them a full dose on alternate nights for a week, then skip a week, then two weeks, then three weeks and then advise a full dose once a month as long as they live.

DR. J. M. ANDERS, Philadelphia: The fact is recognized that chronic hypertension is of the greatest aid in the recognition of chronic nephritis. It is important to recollect, however, that this symptom has not quite the same value in the female as in the male, for the reason that the female hypertension of vasomotor toxic origin is more frequent than in the male. We meet with many cases of chronic hypertension at the time of the menopause due to endocrine causes, and most of them are quite independent of the group so well described by Dr. Riesman. Then again in true exophthalmic goiter, and also in the cases which have been referred to by Dr. Riesman, as "thyrotic symptoms without thyroid disease or exophthalmos," we have instances of chronic toxic hypertension under conditions that do not lead to chronic nephritis as a rule. There is a form of chronic myocardial disease, with which chronic hypertension is often associated,

in which there is more or less myocardial insufficiency, but the blood pressure is abnormally high. There is a vasomotor compensatory mechanism operative in such cases; this is practically proved by the fact that as you strengthen the myocardium the blood pressure falls. This particular variety of myocardial disease is more common in the female than in the male. These subjects are often obese; they have reached middle life and commonly anemia of the secondary type is found in association; and both the obesity and the anemia must be taken into account in the treatment since both are causally related to the myocardial condition. I have seen several cases which belong to the group first described by Dr. Riesman in which cardiac hypertrophy with hypertension, and the basic systolic murmur, angina and elevation of temperature were the principal symptoms. To the causes which he mentioned of this condition, menopause and mental worry, I would add overeating with insufficient systematic muscular exercise. The murmur is not due to stenosis at the aortic orifice but doubtless to a roughening of the valve segments or of the intima of the aorta. The slight fever is most probably due to an associated aortitis, and if we accept Allbutt's view, the aortitis accounts for the angina pectoris. Of the two cases I have seen which belong to this group one patient died of angina pectoris and the other has recently had her first attack. In regard to the treatment of this condition, I feel that the two most important elements are: first, proper restriction of the diet, particularly the fat-forming elements, and, second, systematic physical exercise, as Dr. Bishop has pointed out, provided the arterial changes referable to the aorta are not too far advanced. If there is extension of the aortitis to the coronaries with marked arrhythmia, then, of course, this question of systematic physical exercise must be taken up with great care and caution.

DR. DAVID RIESMAN, Philadelphia: What Dr. Pratt says about sclerosis of the aorta is true. However, though there may be arterial changes elsewhere, the peripheral arteries are usually so soft and pliable that unless one is careful to take blood pressures, the circulation will be considered normal. The patients come to us when they are in the state of hypertension. To detect the earliest stages we must, as Sir James Mackenzie suggests, make complete examinations and take full histories of all patients, even if the complaints are trivial. Reviewing the histories of those cases that develop hypertension, it will eventually be possible to know the beginnings of the disease. Something may, perhaps, be learned from the periodic examinations inaugurated by some insurance companies. Dr. Bishop's observations are most interesting. If I lived in New York I should probably agree with him regarding eggs. I am, however, not in favor of a high protein diet in hypertension cases. Patients have told me that they felt better on a diet largely lactovegetarian and they do not want to return to a meat diet. But in the last analysis it is probably more important to reduce quantity than to alter quality. What Dr. Anders says about taking blood pressures, in order to recognize nephritis, is most important, as the blood pressure often gives us a better idea of the duration and gravity of the disease than the urine. Anemia is sometimes an important feature and patients are frequently helped by treatment directed against the state of the blood. Regarding exercise, I believe there are periods when it is better not to allow it. One must be governed by the response of the circulation to physical activity. In many cases golf undoubtedly proves beneficial, perhaps as much by reason of the mental relaxation as for any other reason.

Itch.—"Itch" is a term frequently applied to occupational disease; thus we hear of grocer's itch, barber's itch, brick-layer's itch, prairie itch, hatter's itch, washwoman's itch, lumberman's itch, sugar refiner's itch, etc. While some of these conditions are incidental, many are the result of occupation. The itching resulting from occupational irritants is sometimes due to the irritation due to repeated friction, sometimes to the effects of chemicals (as acids and alkalis) while under other conditions it is due to infectious processes. —S. SOME EXPERIENCES IN NEUROLOGIC
THERAPEUTICS *

CHARLES K. MILLS, M.D., LL.D.

Emeritus Professor of Neurology, University of Pennsylvania School
of Medicine; Senior Neurologist, Philadelphia General Hospital

PHILADELPHIA

PERKINISM AND BURQUISM

Toward the end of the eighteenth century a Connecticut physician, named Elisha Perkins, aroused much interest among the medical profession and the public, especially the latter, by a pamphlet in which he advocated the use of what were termed "metallic tractors" in the treatment of a variety of diseases. The tractors were small rods of different metals the extremities of which were applied to parts supposed to be diseased. Wonderful cures were reported and exhibitions of the value of the tractors were given throughout the country. The fame of the treatment crossed the ocean to Denmark, England, France, and other parts of Europe. Books and pamphlets concerning it were published, but after a decade or two it passed into innocuous desuetude.

Many years after Perkins and his disciples, at first at Milan and afterward at Paris and elsewhere, one Dr. Burq appeared and advocated the use of metals both in the diagnosis and in the treatment of neurotic affections, his efforts receiving attention under the designations of metalloscopy and metallotherapy. Burq published a small book in 1882. He was taken up by Charcot after he had been extensively patronized by the public.

In the ninth decade of the last century I became much interested in the publications of Charcot and Richer on the subject of hypnotism and also in Burquism, which belonged after all in the same domain. I had a series of metallic disks of uniform size made—of copper, zinc, tin, iron, lead, silver and other metals. These are probably still to be found stowed away in some closet at the Philadelphia General Hospital. For my experiments with gold I generally used a twenty dollar gold piece, which, I presume it is unnecessary for me to explain, was not left at the hospital.

Experimentation was carried on not only as regards the external metalloscopy and metallotherapy of Burq, but also into what was termed internal metallotherapy. Disks first of one metal and then another and another were applied to blindfolded patients, especially hysterics, and when the metal to which the patient responded—that is, which created some peculiar sensation under the point of application—was found, this metal was used to dispel, transfer, or in some instances to produce anesthesia and other phenomena. The method was used in efforts to relieve contractures as well as anesthetics and paralyses of presumably functional type. Sometimes when I found that the patient was responsive to a particular metal, I would administer in addition to the external applications, this metal or some of its salts internally (internal metallotherapy). The results, as might be expected, were somewhat irregular, although at times they were rather striking. Soon, however, I tired of these performances, as of my various experiments in hypnosis, which were often interesting but rarely resulted in any permanent good to the

patient. One thing they did was to strengthen the views that I held, even then, as to the importance of suggestion and countersuggestion.

THE SUSPENSION TREATMENT OF LOCOMOTOR ATAXIA

Motchkoukowski of Odessa published a pamphlet in 1883, describing the advantages of using suspension in the treatment of locomotor ataxia, having arrived at his ideas through the accident of observing a patient suffering from this disease apparently obtain relief from the application of a plaster-of-Paris jacket. Professor Raymond, traveling in Russia, observed Motchkoukowski's results and brought an account of them to Paris.

Charcot, whose endorsement brought Burquism into more or less undeserved repute, was also responsible in considerable part for the attention which the neurologic profession gave to the treatment of tabes by suspension. He and his assistant, Gilles de la Tourette, experimented with Salpêtrière patients with what were believed to be gratifying results. The improvements reported by Motchkoukowski and Charcot in some of the ataxic patients were said to be remarkable. Some of these were changes for the better in the Romberg symptom; improvement of gait in walking; diminution of lancinating pains; beneficial effects on sexual power; and better control of the bladder. As might be expected the absent knee jerks and pupillary phenomena were not favorably affected.

Neurasthenia, Friedreich's ataxia, and paralysis agitans were other diseases reported as improved by suspension. The rationale of the improvement was not explained with any clearness. It was supposed, however, that the spinal circulation was benefited and that some stretching of nerve fibers occurred, the latter supposition being altogether doubtful. At that time the fact was not generally recognized, as at present, that locomotor ataxia, like general paresis, is a true syphilitic disease due to the presence of spirochetes.

The apparatus used by Charcot was that contrived by Dr. Sayre of New York in the treatment of his cases of spinal caries by suspension. Charcot first published his results in a lecture given Jan. 15, 1889. It is noteworthy that many patients with tabes reported as having undergone this treatment expressed a sense of having been much benefited by the suspension. This is probably to be explained by the well known optimism of tabetics.

Dr. S. Weir Mitchell, in the *Medical Times*, April 13, 1889, described an improved apparatus for suspension, the chief peculiarity of which was that the suspension was in part made from the elbows, the arms being held to the side by a strap, and additional suspending apparatus being applied to the chin and occiput.

Cases were reported to Philadelphia societies as to many others. The Orthopedic Hospital and Infirmary for Nervous Diseases, of this city, and not a few other institutions, were supplied with suspension apparatus, and some enterprising neurologists saw to it that their offices were similarly equipped. The merry dance—or rather the merry hanging—went on for a time with what was supposed to be advantage to the suffering tabetic. This treatment soon passed to the therapeutic limbo.

THE SURGEON AND EPILEPSY

With epilepsy I have had many interesting experiences, both medical and surgical. I will speak here

* Read before the Section on Nervous and Mental Diseases at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

only of the latter. From times remote, considered in the light of a century or a half century, numerous suggestions and experiments have been made regarding the relief and cure of epilepsy. Very early in my professional life I knew something of the efforts that were made on the basis of the old "reflex" hypothesis to rescue the unfortunate epileptic. Children were circumcised; women were deprived of their ovaries and occasionally of the clitoris; a nerve in the hand or the foot or at the root of a tooth or somewhere else, according to the apparent indication, was resected, and much more of a similar sort was done to exorcise a constitutional disorder which refused to respond to the rites employed to banish it.

The term epilepsy is here used in a broad sense to cover several forms of convulsive seizures. Long ago the trephine or trepan was sometimes used without any particular care or skill or selection of site for the relief of spasms. Bloodletting was at one time so heroically employed in the hope of relieving epilepsy as to become almost entitled to be included under surgical procedures.

When, some fifty years ago, the modern doctrine of cerebral localization obtained a sure footing in physiology and neurology, operations soon began to be suggested and performed, the surgeons being guided as to the choice of site by the principles of localization. Cranial fracture, localized hemorrhage, abscess, and tumor became the frequent objects of surgical intervention, often with marked or even brilliant success. It is not my intention, however, to go into this subject at any length. I merely refer to it to introduce a few remarks regarding two or three of the surgical procedures which since then have been generally laid aside.

One of these was cortical excision, which was advocated by Horsley and others, and for which I was sometimes responsible. The idea in these cases was that even in the absence of any clear evidence as to a gross lesion, if the spasm could be shown to be of a local or jacksonian type, trephining should be employed. After fixing the exact center or area likely to cause such spasm by means of faradization of the exposed cortex, this center or area was then excised. On the whole, the operations of cortical excision, of which a considerable number were performed, did not prove successful, although in some instances the spasm did not recur for a long time after the operation. One of the results in these cases was, of course, that a local paralysis in the limbs or part controlled by the centers excised necessarily occurred. This in most cases became less and less marked and would not have contraindicated operation if a positive relief of the spasmodic attacks had been obtained.

I had brought under my observation a number of cases of so-called idiopathic epilepsy in which operation was suggested or in which an opinion was sought as to the propriety of such operation. In these cases jacksonian spasm; that is, a monospasm or hemispasm involving the face or arm or leg, or one or two of these parts, was usually present as part of the general motor paroxysm. I soon learned that a frequent, if not the most frequent, source of so-called jacksonian spasm was idiopathic epilepsy, a fact to which attention was called by Collier. As I spoke of the matter in one of my papers, the jacksonian attacks occur inside the general epileptic seizure and their presence simply emphasizes an opinion long since expressed by that great neurologist, Hughlings Jackson, that if epileptic fits were

sufficiently well observed it would be found that in nearly all cases such seizures began with some form of local spasm. This, of course, is often overlooked and even acute, sharp-eyed observers, whom I have frequently employed in my wards, have sometimes failed to note its occurrence, so quickly does the initial spasm radiate to other parts and eventually to all portions of the body musculature. In a number of cases which came under my observation and in which I was responsible for the procedure, trephining, guided by these jacksonian manifestations, was used, no lesion being revealed. In some cases, however, considerable benefit in the way of suspension of the paroxysms occurred.

In recent years the surgeon has extended his efforts for the relief of epilepsy to the abdominal cavity. One distinguished surgeon, some dozen years ago, recommended for the relief of epilepsy the operation known as appendicostomy. Various considerations were advanced in the discussion of epilepsy at the time of this recommendation, but into these I cannot take the time to go. They were based chiefly on the idea that epilepsy was due to some form of intestinal toxemia. A hole was made into the intestine in the appendical region, and a course of irrigation of the colon was begun, usually with warm water. This, of course, was at first under the direction of the surgeon himself and of the nurse, but later, in some of the cases in which this treatment was employed, the patient was taught to treat himself while lying in bed, by passing a tube through the opening into the intestine and then allowing slow irrigation to occur, the fluid and whatever it carried with it being received in a bed pan or other receptacle. A very few striking results were reported; that is, cases in which the epileptic or epileptiform attacks had ceased for several months or perhaps longer. So far as I know, no results of absolutely permanent value were obtained. This was a rather striking procedure, but one, it always seemed to me, not likely to become acceptable to the patient who was expected to keep on with this process of irrigation on his own hook.

A western surgeon more recently described the operation of ecostomy which he used in cases of constipation mechanically produced, and also for the treatment of epilepsy. It was practically the same operation as that to which I have just referred, except that the opening was perhaps an inch or two away from the appendical orifice.

The same skilful and distinguished surgeon, in the course of his operative procedures for the relief of constipation mechanically produced, came across some constipated epileptics in whom the frequency of the attacks was much diminished by the operations performed, which were usually on the colon and need not here be described.

Going a little further into the subject of epilepsy, he learned, what I am sure has been the common knowledge of neurologists, that most epileptics were subject to constipation and therefore, perhaps, the constipation and the epilepsy had the relation of cause and effect. He advocated procedures similar to those which were used for constipation in nonepileptic patients. Noting that, while epileptics were generally of constipated habits, the multitude of the constipated were only in rare instances the victims of epilepsy, he found it necessary to look a little further into the subject. Doing this by methods which are well known to the profession, he came to the conclusion that epilepsy was due to

some form of bacterium or bacillus which probably originated in the duodenum, and whose habitat eventually became the great intestine, or colon. The steps that followed were rather extraordinary and yet I suppose logical from the standpoint of this observer. Not being able always to establish a proper fecal current through the torpid, diseased and absorbing colon, he came, in the process of time, to the idea of getting rid of the colon, and in this way the operation of colectomy was introduced, and not a few epileptics were reported as cured or greatly benefited by this extirpating operation.

Personally I cannot help thinking that this large part of our intestinal tract called the colon has some valuable function in the average human being, and while it may be a convenience to the individual at times to have his bowels short-circuited from the ileocecal region to the anus, this procedure may have its physiologic and pathologic drawbacks.

Eventually the surgeon to whom I have referred, because of the negative results of laboratory investigations made by others, and also under his personal supervision, was obliged to withdraw his endorsement of the idea that the special convulsion-producing germ had been found in the intestine.

DENTAL INFECTION AND THE PSYCHOSES AND NEUROSES

Some years ago I presented a brief paper before the Stomatological Society of Philadelphia on "Obsessions Regarding the Mouth and Teeth." After discussing the subject of obsessions in general I gave details of a few interesting dental cases. One patient had the idea that she was suffering from some disconcerting affection at the root of a tooth. This was removed. The distress then began to change its dental habitat, and the patient went through a series of tooth-removing campaigns, but still no relief was obtained. When I first saw her she had only one tooth left, and this was soon extracted by a dental surgeon. At last a distinguished oral surgeon engaged in a vain search for her elusive pain by probing the antrum. She became an alcoholic habitué, and eventually died broken down by her obsessions and her excesses.

In another case the mind of the patient was turned to her teeth until they were all removed and plates were substituted, and later, from time to time, no relief being obtained, she had one plate after another made until the number had increased to twenty-two.

It has seemed to me in recent years that the obsessions regarding the teeth have taken possession of the medical profession. Numerous papers have been written about the rôle of focal infection originating at the roots of the teeth in the causation of mental and nervous maladies. Teeth by the score, many of them of excellent quality, have been sacrificed, and in not a few instances cures or great benefit have been alleged as a result of the treatment. The matter is one of much importance, and has been emphasized by my observation of a number of victims of the dental forceps.

Dementia praecox, manic-depressive insanity, epilepsy, neurasthenia, hysteria, and psychasthenia are only a few of the diseases that have been attributed to dental infection.

The usual procedure in private practice is for the patient, who has probably been seen by one or several neurologists or alienists, to seek, because of the wide exploitation of the subject, a physician who is known

to lay stress on the importance of tooth infection. The patient is then sent to the roentgenologist, who almost invariably discovers and is able to mark out a series of alleged abscesses, which are in some instances at least, absorptive lacunae, innocuous foci, or mistaken observations. I do not mean to say that real abscesses are never demonstrated, but as one of my dental friends has pointed out to me, these are frequently not to be found even by the probe in the hands of a skilful surgeon. In a majority of cases, however, the teeth are sacrificed on this altar of focal infection.

The tooth extraction sometimes has an unintended outcome. The patient's mind, already obsessional from the very nature of the malady, becomes fixed on the teeth as a source of his ailments, and what is perhaps worse, the same obsession takes hold of the minds of relatives or guardians. After three apparently good teeth had been removed from one of my patients, she, like the first patient cited in this section, became possessed with the idea that the work of tooth extraction should go on, this obsession pursuing her at all times.

In another case of dementia praecox, as I was told by the mother and the caretaker, the boy had his teeth roentgenographed. Nothing was found, but the advice was given that it would be a good thing to remove a couple of teeth anyhow.

One of my medical friends had a rather interesting experience in connection with this subject. An old gentleman, who was not only a patient but a family connection, had suffered with pain in the neighborhood of the sacro-iliac synchondrosis, and had been treated therefore by the usual therapeutic procedures for affections of this locality, with, however, only partial relief. A consultation came about with a physician and a roentgen-ray specialist, and one of the consultants without any examination of the mouth or jaws expressed the opinion that the probable source of the trouble would be found in abscesses at the root of the patient's teeth. My friend, after allowing him to go on with his dissertation a short time, said casually, "It may be, but I must remark that our patient hasn't had a tooth in his head for the last five years."

LINEAR CRANIECTOMY AND OTHER METHODS OF CRANIECTOMY FOR THE RELIEF OF IDIOCY OR IMBECILITY

Lannelongue of Paris¹ reported his experience in two cases of microcephalic idiocy in which he performed the operation of linear craniectomy. One of the patients was apparently benefited, although, as the recorder notes, training of the patient was resorted to in addition to the surgical procedure. My first experience with this operation was with Dr. W. W. Keen of Philadelphia, who, shortly after the publication of Lannelongue's article, began to make use of the operation for cases similar to those described by the French surgeon. The usual procedure was, with certain technical precautions, after lifting a flap of the scalp of sufficient length and breadth, to cut out a strip of bone about one-fourth inch in width and about 4 to 6 inches in length. Dr. Keen published several articles describing his experiences with this operation. As he has recently informed me, he finally gave it up, the results obtained not justifying a continuance of the surgical measure.

1. Lannelongue: *L'Union méd.* Series 3, 50:42 (July 8) 1890.

Dr. C. L. Dana of New York published two articles on the subject.² He had the surgeon undertake the procedure described by Lannelongue and Keen with, however, some modifications as regards the character and extensions of the bony removals. Dana, like Lannelongue and Keen, believed that he obtained a few good results which strangely enough he ascribed to the "pedagogic" influence of the surgical procedure. I must confess that this explanation never strongly appealed to me. It seemed to savor of the explanation of the treatment of delusions by the repeated administration of shower baths until the insane subject finally concluded it was better (for the time being, at least) to give up his delusions rather than further endure the punitive measures. These delusions usually promptly returned when the patient was assured he was out of further danger from the cold douching. The operations were also to some extent reminders of the disciplinary measures—carried out with clubs, whips, or even incisions—in order to improve the manners and morals and presumably the intellects of obdurate criminals.

The wonderful theory, however, advanced to support this procedure was usually not pedagogic or disciplinary, but was based on the idea that by removing strips or variously shaped pieces of bone from the cranium the retarded brain of the microcephalic or demimicrocephalic idiot or imbecile would then be given an opportunity to expand and develop. It was sometimes argued that the fontanels and sutures of the infantile skull had closed prematurely, thereby holding in check a brain that would otherwise develop to fair proportions. The argument in favor of the operation, however, was, to my mind, founded entirely on false premises. It entirely overlooked the fact that the arrest of the brain, like the arrest of the skulls in these cases, is due to biopathologic processes, hereditary and embryonal. As my colleague, Dr. James Hendrie Lloyd, once remarked during a discussion of Lannelongue's operation at the Philadelphia Neurological Society: "It is not possible to improve the quality of a bad nut by making a hole in the shell which encases it."

My chief object for recalling this operation, as in referring to much else in this paper, is to show how prone neurologists and surgeons have been to have recourse, without due consideration of principles, to procedures that could not possibly be of any practical service.

Operations in porrencephalic and hydrocephalic cases have proved as futile, in my experience, as the craniotomies for the microcephalic. It proved a great temptation to myself, as well as to others, in the earlier days of my localization experiences, to operate in cases of convulsion, with or without mental deficiencies, when the sites for such operations could with accuracy be easily indicated. In the main, these cases were examples of porrencephaly, the residua of previous hemorrhages, or of focal encephalitis after various infective disorders. Due consideration was not given to the significance of the cavities, which were in fact in most instances, whatever their origin, conservative or partly protective. Many of the cases ended disastrously, if it can be regarded as disastrous to have such patients perish in the hands of the neurologist and surgeon. In a limited number of cases in which

the cysts were shallow some good seemed to result, but in others, if the patients escaped death, there was often an increase in the excitability of the cortex.

Tapping the ventricles for hydrocephalus was in my experience equally lacking in efficacy, even when the operation was accompanied, as it infrequently was, by an imperfect effort at slow compression of the skull.

NERVE STRETCHING

About thirty-five years ago, the operation of nerve stretching for a variety of sensory and motor disorders began to be used. John Marshall in 1883 delivered the Bradshaw lecture before the Royal College of Surgeons of England on "Neurectasy or Nerve Stretching for the Relief or Cure of Pain." This lecture, which was carefully prepared and founded in considerable part on experimentation, helped to give the operation a scientific status. Dr. Christian Fenger³ of Chicago and Dr. W. W. Keen of Philadelphia, among others, made valuable contributions to the subject of nerve stretching. Unquestionably this operation was sometimes successful in relieving severe pain, especially when it seemed of a purely neuralgic type. The operation was also resorted to occasionally, but with less favorable results, for tabetic pains.

Among the motor disorders in which nerve stretching had varying success, were facial tic and spasmodic torticollis, many cases of the latter affection really belonging in the category of tics, although this was not at first generally recognized. I recall two cases of facial tic in which operation with good results was performed by Dr. Keen. The stretching force exerted in these cases usually amounted to 4 or 5 pounds of weight. The nerve was exposed near the stylomastoid foramen, and the stretching was done steadily—not with sudden force. The first result of this operation on the facial nerve was complete paralysis, the tic disappearing. The paralysis was gradually recovered from, and in one or two instances which fell under my observation, without return of the spasm. This, however, was not the usual result, and the operation was soon largely abandoned. The cause of such tics was either partial nuclear degeneration or a faulty cortical discharge, neither of which could be banished by operative procedure.

I had considerable experience with spasmodic torticollis. One of my earliest papers was concerned with this affection. It is not necessary to tell an audience of neurologists that this is one of the most intractable of diseases. Stretching of the spinal accessory nerve was employed for its relief, but without success. Equal want of success, however, attended other operations, as for instance tying the accessorius with silver wire, sectioning it, cutting the muscles presumably involved, and excising the spinal nerve roots. The lack of success in this operation seemed to be due to the fact that the spasmodic disorder was one which probably had its seat in instability of the motor cortex. When the affection was closely studied it was found to be not a neural or muscular affection, but a disorder of movement involving a group of cooperating muscles.

Shortly after the period in which nerve stretching was advised and resorted to for the relief of pain and local spasms, the operation began to be recommended in the treatment of several forms of sclerosis, as symmetrical lateral sclerosis (a rare affection), dissemin-

² Dana, C. L.: *A. J. M. Sc.*, New Series 110: 24 (Jan.) 1896.

³ Fenger, Christian: *Collected Works of Christian Fenger, M.D.*, 1840-1902, Philadelphia, W. B. Saunders Company, 1912, Vol. I.

nated sclerosis, and spasmodic paraplegia. In one of my cases of disseminated sclerosis nerve stretching in the lower extremities by the method without cutting; that is, by forcibly flexing the extended leg on the trunk, was used, and no beneficial result having been obtained, Dr. Keen stretched the sciatic nerve by a cutting operation in which after exposing the nerves he subjected them to a slowly continued pull corresponding to about 25 pounds of weight. This operation, as might have been expected, also resulted in failure.

Looking backward on these surgical procedures, their futility is easily recognized. It is evident that, at the most, they could have only temporarily affected the spasmodic disturbance. In other words, the operation was not based on a proper consideration of the nature of the disease, and therefore was not a really rational procedure.

GLANDULAR THERAPY AND ABDERHALDENISM

Foremost among the methods of glandular therapy to be tried out by me personally was the use of preparations of thyroid. In a well known line of cases these proved invaluable, as in myxedema and myxedemoid and cretinoid cases, in adipositis dolorosa, and in forms of adipositis not of the Dercum type. This treatment in a strict sense was not curative, but when the amount which could be administered without too much constitutional reaction was determined by trial, the various preparations of the glands of the sheep or of other animals were given with continued advantage and sometimes with remarkable success. As a rule, however, it was necessary to keep up the administration as a part of the regular diet of the patient.

In a limited number of cases of epilepsy I have had decidedly beneficial results from the use of thyroid with bromids and arsenic and special forms of diet, as for instance the so-called purin-free diet. In addition to thyroid, pituitary preparations have also proved of value in cases of epilepsy with dyspituitarism.

With preparations of other glands, like testicle, ovary, mammary gland, and suprarenals, my experience has not been promising, although I have seen some benefit accrue from the use of suprarenal or pancreatic extracts, especially in melancholia and epilepsy.

In connection with this question of glandular therapy, that of glandular removal comes naturally into the foreground. Every neurologist and alienist will remember the rage in the early days of aife, that is, of aseptic and antiseptic, surgery for removing ovaries for the relief or cure of neuroses and psychoses. The fashion was so rampant for a time that there promised to be partial race suicide by way of the surgeon's knife. Directly or indirectly, I came in contact with much of this work. My experience might be included in the simple statement that nine tenths of such removals did not result in the relief of nervous maladies. In a considerable percentage of the cases the postoperative mental or nervous state was such as clearly to indicate that the operations had done harm rather than good. These operative procedures in some instances were the source of traumatic affections, especially troublesome adhesions, and in other cases of new or more confirmed obsessions. It is rather interesting to note the contrary manner in which the two sexes were treated as regards the sexual glands. The woman suffering from a variety of mental or

nervous disorders had her ovaries removed, while, forsooth, the man afflicted in the same or a similar manner was treated by the administration of testicular preparations. So far as results were concerned, however, it mattered little; one was about as effective as the other.

When a few years ago (about 1912) the investigations and theories of Abderhalden of Halle were published, a new stimulus was given to glandular therapy. I do not feel competent to pass fully on the subject of Abderhaldenism, as I have found it somewhat difficult in the limited time and opportunity at my disposal to determine from scientific considerations the value of the methods both of diagnosis and of therapeutics suggested by a study of the protective or defensive ferments of the body. Some of my own patients, and other patients of whom I have knowledge, have been subjected to these investigations and have had made on them therapeutic applications of the results of such investigations. The cases to which I refer particularly include examples of dementia praecox, melancholia, and hysteroneurasthenia, especially the first.

As the result of painstaking Abderhalden tests, guarded by all the precautions suggested to those who work in this field, certain glands have been determined as most likely to be beneficial because of their supposed or known antagonistic action to other glands, which the investigator has found to be dysfunctioning. Preparations of testicle, for instance, have been used when the pituitary was the offender; of the suprarenal when the suprarenal was at fault; or of the pancreas when the indications were of pancreatic infantilism or deficiency. For instance, certain glands are given to replace a supposed deficiency in the corresponding glands, and their opponents are administered to subdue hypersecretion. Results apparently beneficial but usually temporary were obtained in some of these cases. In a very few instances more permanent results were in evidence. I have never been thoroughly convinced, however, that the clinical course of a genuine case of dementia praecox was halted for more than a brief period—a period similar to that which one sometimes observes in these cases without the use of Abderhalden or any other form of therapeutics.

The observations of Ludlum on psychopathic patients cured or greatly benefited by the use of either acid or alkaline preparations—according to the result of investigations into the acidity or alkalinity of the saliva, urine, stools, perspiration and blood—in combination with preparations of ovarian gland when the blood pressure is high, and of suprarenal extracts when it is low, are of decided interest and open up a field of therapy for the neurologist and alienist.

One of the points which has always impressed me when studying reports of this sort and the theories on which the treatments suggested in such records have been based, is that due consideration is not given the teratologic origin of the affections which it is hoped to cure by changed acidity or alkalinity, or by these combined with the use of glandular preparations. The fact is too often overlooked that the glandular condition, and even the state of acidity and alkalinity in some instances, are themselves only a part of an ordained embryonal state which cannot be successfully combated, or at least cannot be attacked with full success on chemical and other theories of such limited import.

ANTISCORBUTICS: II

In a previous issue of *THE JOURNAL*,¹ reference was made to some of the experiences which have led to the development of diverse sorts of antiscorbutic products available for the purposes of infant nutrition. It is not necessary to refer back to the older expeditions in search of the North Pole or to the experiences of our Civil War to learn how essential antiscorbutic foods may be to an adult as well as to the growing infant. The changes in our food supplies have altered the dietary habits of mankind;² and, although in normal peace times the tendency toward a liberal supply of varied foods is likely to avert widespread deficiencies of essential factors, this is far from being the case under war-time conditions. Scurvy made its appearance in Europe among troops and civilians when the exigencies of the situation in which they were inadvertently placed compelled them to subsist on unsuitable foods. This does not necessarily mean that the energy furnished was insufficient or that the protein was inadequate; but it has shown that even in the midst of plenty the quality of our foods may be dangerously defective.

The knowledge that heat may affect the stability of vitamins and more particularly the antiscorbutic property of foods has focused attention on the effects of cookery, canning and various other modes of food preparation and preservation on the integrity of the accessory food factors. We shall not claim the ability to render a final judgment as to either the safety or the innocuousness of any of the varied methods of conservation. A few references to the outstanding facts ought, however, to serve as an indication of the great uncertainties which have been raised, and the probable considerable significance of the questions at issue for practical dietetics. The keynote was sounded by Holst seven years ago. The striking demonstration of the loss of antiscorbutic potency as the result of desiccation and cooking furnished by *Givens and Cohen*³ of

Yale with regard to cabbage and potatoes has been substantiated at the Lister Institute in London.⁴ We are told that, so far as animal experiments can be depended on to furnish evidence, there is a loss in antiscorbutic properties of more than 93 per cent. when cabbage is dried at a low temperature and stored subsequently for from two to three weeks at laboratory temperature. After drying and storing for from five to six weeks at laboratory temperature, a further loss of antiscorbutic properties is suffered. After storage for three months, nearly all the protective value of the fresh material is lost (about 96 or 97 per cent.). The fact that less loss through desiccation takes place if the product is first steamed or plunged into boiling water suggests at once that something other than mere heating or desiccation is concerned in the deteriorating influences of these preservation processes.

From the standpoint of culinary food preparation, *Delf*⁴ suggests that these facts have some bearing on methods of cooking green vegetables, and indicate broadly that the least loss of antiscorbutic properties will be obtained by cooking green vegetables for a short time at a higher temperature rather than for a longer time at a lower temperature. *Hess and Unger*⁵ have lately reported that carrots lose much or all of their antiscorbutic potency through cooking. They have, furthermore, called attention to the added factor of the maturity of the plant. As they express it, from a nutritional standpoint carrots cannot be looked on as a uniform article of diet. There is a marked difference in various lots of carrots, and probably also of other vegetables, according to whether they are fresh and young, or are old. It was found, for example, that if, instead of employing the carrots which were ordinarily fed to their laboratory animals, they gave the same amount of fresh young carrots, plucked only a few days previously and cooked, not only did the animals not develop scurvy, but they gained steadily in weight for a long period.

*Hess and Unger*⁵ remark that the freshness and age of the vegetables sufficed also to enable them to retain their antiscorbutic potency after dehydration. This is a statement of considerable importance because it points to a further variable that may need to be considered in evaluating food preparations from the standpoint of their antiscorbutic effects. If, to the problem of the effect of heat, oxidation, preliminary treatment and age of the fresh product, there is added the question as to the possible influence of different reactions—of acid and alkali as they occur naturally in foods or are added incidental to their manipulation

—the complexity of the project of retaining the antiscorbutic potency becomes more apparent.

This is a time for cultivating the "open mind" in reference to the true nutritive value of conserved foods. If some desiccated vegetables have proved to be devoid of antiscorbutic efficiency, it must, nevertheless, be admitted that the loss can probably be averted entirely or partially when the conditions which determine it are definitely ascertained. Fruit juices have already been concentrated, and tomatoes have already been dehydrated without becoming impotent in respect to the factor under discussion. Hess and Unger assure us that it would be an error to infer from such experiments as are now on record that milk necessarily loses its antiscorbutic potency when it is reduced to a dry state. Enough specific instances of contradictory facts are on record to warn us, on the one hand, against condemning canned goods or dehydrated vegetables or their analogues from the standpoint of their vitamin potency; or of praising any of them without specific information as to each product. The offhand statements which are beginning to emanate from partisan or inadequately informed sources must not be accepted. The time is not yet ripe for "expert opinions" that are all comprehensive in their information. Knowledge in relation to vitamins is in the making. Fortunately, at the point where chemical analysis utterly fails, the physiologic experiment is proving to be a dependable guide. Let us get the facts first of all.

HOW SHALL WHEAT BE USED AS FOOD?

Whether or not our wheat supply is advantageously used depends on a variety of factors, some of which already have been considered. It is evident that wheat flour can be "stretched"; that is, the nutrients can be increased by raising the current extraction of from 70 to 75 per cent., represented by patent flours, to from 85 to 88 per cent. by simply including some of the wheat germ. From the producers' standpoint it must be acknowledged that, owing to the fact that the germ-containing portions spoil more quickly, losses in the trade would undoubtedly occur if all the wheat in America were milled either to a European war standard of from 85 to 88 per cent., or prepared as whole wheat flour and distributed through the American market as at present controlled. Furthermore, even the enthusiast must be forced to admit that breads made from flours of high degrees of extraction have not gained popularity. Taylor,¹ who has had exceptional opportunities to study the war bread situation, asserts that "the revulsion against this bread has been audible in every country; the people have repeatedly petitioned that they be given less bread and better bread." Finally, one cannot overlook the repeated reports that the breads prepared from high extraction flours do not

agree with some individuals. Here it must be admitted, however, that apparently the causes for any disturbance of intestinal function may lie in changes produced in the bread by the germ fraction rather than the bran; for thousands of persons use with apparent impunity graham breads made of flour prepared by returning bran to standard flour.

A somewhat novel aspect of the subject has been presented through recent investigations by Osborne and Mendel,² to whom we owe fundamental researches on the nutritive value of proteins from different sources. They have shown that flour, when used as the sole source of protein, is inferior to other foods in maintaining adult rats, and especially in promoting the growth of the young, but that when the wheat proteins are combined with about one third of their weight of proteins furnished by eggs, milk or meat, they are so greatly enhanced in value that flour is thus used most advantageously. These investigators point out that, since the nutrients of bran are poorly utilized by mankind, a waste of food, though probably not large, results when the bran is included in the flour.

Although the constituents of the embryo have a high nutritive value, the embryo forms so small a part of the entire kernel, and so impairs the keeping qualities of the flour, that probably the nutritive advantages of including the embryo in the flour are more than counterbalanced by the practical disadvantages. On the other hand, when the bran is used in the production of meat and milk, it is converted into proteins which serve to supplement the wheat proteins in human nutrition far more effectively than bran proteins do. To quote the observations of Osborne and Mendel: "Bran and embryo together form about 17 per cent. of the wheat kernel; the endosperm, from which flour is made, forms the remaining 83 per cent. About one half as much flour eaten with the animal products, in such proportion that one third of the protein is furnished by the latter, is capable of satisfying the protein requirements as when flour alone furnishes all of the protein."

If, therefore, about 80 per cent. of the wheat kernel can be so improved in nutritive value by adding animal products to the diet that a much smaller amount of flour will satisfy the protein needs of nutrition, it may well be that the use of the by-products of milling for the production of meat, milk or eggs will result in a greater economy in the use of flour than if these were used directly for human food. In other words, since by far the greater part of the flour used in this country is eaten in combination with those food products which successfully supplement the nutritive deficiencies of its proteins to a far greater extent than do the bran and embryo of the entire kernel, no practical advantage on this score can be expected by con-

verting the entire grain into flour. Bread and milk, eggs on toast, and the sandwich in its diverse varieties, represent supplementary combinations that find their justification in the latest scientific researches. Man cannot live on bread alone, even if it be made of whole wheat.

THE DIAGNOSIS OF TUBERCULOUS COLITIS

Tuberculous lesions of the intestine are frequently found at postmortem examinations (from 60 to 90 per cent.) whenever a tuberculous process has existed in the lungs for any length of time. The inevitable lodgment of some of the tubercle bacilli which pass almost continuously along the gastro-intestinal tract of the tuberculous patient is to be expected. Clinical recognition has, however, lagged far behind the reasonable expectancy that postmortem experience seemed to warrant, perhaps because we concentrate our clinical attention so firmly on the pulmonary involvement that we disregard the rest of the body, or explain away possible intestinal symptoms on the basis of the general intoxication; more likely, though, because the great majority of the intestinal lesions, especially if located above the ileocecal junction, give rise to only an indefinite symptomatology.

Even with our attention focused on the abdomen as a result of suggestive symptoms, the means of certain diagnosis are still lacking. The mere finding of tubercle bacilli in the stool is of no value, for in virtually every open pulmonary case we get the same result on careful examination. This uncertainty is the more unfortunate because medical or surgical aid, if it is to be of value, depends entirely on the early recognition of the disease extension. When once the stage of distinct abdominal tenderness, of severe pain and of intermittent diarrhea has been reached, our corrective measures are virtually useless.

As an aid in just this situation, Brown and Sampson¹ emphasize the value of systematic roentgen examination as a routine measure in tuberculousis, basing their conclusions on a study of 110 cases. Two definite observations have been contributed by them: In tuberculous ulcerative colitis there exists a well marked hypermotility of the large intestine, particularly of the cecum, together with a distinct spasm of the cecal musculature. These findings, when observed in a tuberculous patient, with or without definite abdominal symptomatology, seem of considerable diagnostic importance. In the clinical and roentgen correlation, Brown and Sampson found that of sixty-eight moderately advanced pulmonary cases, forty-four were negative, fifteen doubtful and nine positive on roentgen examination. Of the nine positive cases, four were proved positive at operation and five cases did not come to operation. Of twenty-two far

advanced pulmonary cases, five were doubtful, the balance positive. Of these positive cases, nine were verified at operation, three resulted fatally, and five did not come to operation. Contrasted to these moderately advanced and advanced cases, the examination of incipient cases (eleven in number) yielded only three that were positive. Of these, one was proved at operation, one terminated fatally, and one did not come to operation.

While our diagnosis of tuberculous colitis has thus advanced considerably in this regard, the recognition of tuberculous ulceration of the intestine above the colon is still a baffling problem and one that, for the time being, will bring into demand the greatest amount of medical judgment and careful analysis of the patient. It is unfortunate, too, that therapy (apart from surgical measures), even when considered merely from the standpoint of amelioration, is quite unsatisfactory. Saxtorph² suggested the intravenous injection of calcium chlorid, and Fishberg³ has reported some success in a limited number of cases. At times a single injection (5 c.c. of a 5 per cent. solution) is said to relieve the distressing intestinal symptoms. When, however, the ulceration is extensive and the inflammatory reaction about the lesion includes areas of localized peritonitis and of adhesions to neighboring viscera, the chance even for palliative measures is poor.

FACTS AND FANCIES CONCERNING LACTATION

What incites the development of the true secretory tissue of the mammary gland and provokes the process of lactation continues to be an interesting subject for speculation despite the attempts of numerous investigators for years past to solve the riddle. There seems to be convincing evidence that the development is not necessarily evoked by the central nervous system; for there are duplicated records of the growth of the glands and the secretion of milk at parturition in animals in which all nerve connections of glands were severed during pregnancy. Current tendencies in physiology have given free play to the hormone hypothesis which assumes the liberation and distribution, from some gland or organ, of a chemical substance which acts as the stimulus to the elaboration of the mammary function. The uterus, placenta, fetus, corpus luteum and other structures have been called on in turn to account for the liberation of the galactagogue. They have been alleged to act as the sources of excitation or inhibition; and, indeed, many of the theories concerning mammary development can marshal potent facts in their defense. Now and then, however, nature furnishes a stumbling block which

furnishes the occasion for investigations in new directions.

A recent instance of a well authenticated observation illustrating the inadequacy of current hypotheses is cited by Hill¹ of the Maryland Experiment Station. A suckling kid spontaneously commenced to secrete milk without having reached sexual maturity, and without udder manipulation or any other known stimulus to mammary growth. There are on record numerous instances in which young animals have been brought into lactation by being suckled or by having the udder manipulated; hence the oft made assertion that a mechanical stimulus is a fundamental factor in the genesis of milk secretion. The kid observed by Hill, however, had not reached sexual maturity, so that, as he points out, any theory of mammary growth or milk secretion involving the ovaries, corpora lutea, fetus or placenta is not applicable.

Of further interest in this rare case is the observation that the nonremoval of the milk for nineteen days from the lactating kid did not inhibit the secretion as it commonly does in analogous cases of adult milk producers. The milk produced had the composition of normal goat's milk for months, even when the animal was milked at intervals one week apart. None of the milk secreted resembled colostrum. Hill suggests that colostrum secretion must be caused by some special stimulus due to pregnancy and is apparently not associated with the commencement of milk secretion, as was formerly supposed, unless there is an accompanying pregnancy. Here are unique facts of a sort that could doubtless be multiplied if attention were concentrated on the subject. Even with the aid of the obscure and undemonstrated theories of the newer endocrinology, who shall venture a tenable physiologic explanation?

Current Comment

WATER SUPPLY IN PALESTINE

The reclamation of Palestine by the British has at last fully opened the Holy Land to the enterprise of the West. Captain Carson, of the American Red Cross Commission which followed General Allenby, tells us that the first problem of improvement encountered was that of water supply.² That part of Palestine south of Beersheba has been piped with water from the Nile by British royal engineers with American equipment—the realization, it is said of a dream thousands of years old. "Several million gallons" a day are pumped from the canal near Kantara across the Suez Canal into Palestine. At Kantara, rapid sand filters are used. The pipes are laid at least 18 inches

deep in the soil or sand of the desert in order to protect them and the water from heat. North of Beersheba there is plenty of water under the surface, though very little, owing to the geologic formation and meteorologic conditions of Palestine, remains easily available. On the western slopes, however, the valleys form excellent reservoir sites for collecting the winter rains, though they would often have to be treated to prevent loss by percolation. The problem of the water supply of Jerusalem has been attacked by such noted men as Hezekiah—who constructed a tunnel which is today an "almost unexplainable" engineering feat—Solomon, Pontius Pilate and Herod. In the spring of 1918, the British, using much of the Roman work, installed a 6-inch line from the springs of Wady-el-Arub, about 16 miles south of Jerusalem, through which more than 200,000 gallons a day are now flowing into the city. It is said that Jerusalem could be furnished with more than 20,000,000 gallons a day of pure water. Almost every house in the city has its rainwater cistern, and these, with proper inspection by the newly organized health department, are being filled with safe water. It is to be expected that the disappearance of the picturesque water venders of Jerusalem will be accompanied by the passing of the terrible water-borne diseases prevalent under Turkish rule.

THE THERAPY OF BUCCAL CANCER

Connected with the subject of the therapy of buccal cancer are two great factors. The first is that of early diagnosis—a factor of paramount importance in any case, but in none more so than in cancer of the buccal cavity. There is little excuse for failure in this respect, yet it is of frequent occurrence. There still are physicians who profess a great "fear of the knife," and are willing to carry patients for weeks and months until the disease has made such progress that the use of a knife does, indeed, become a fearsome thing. There is a second group of men, intelligent and honest, who, because the patient gives a history of chancre or a positive blood Wassermann reaction, forget the possibility of cancer in the presence of an ulcerating sore on the tongue and lose precious time in a vain endeavor to cure the lesion with arsenphenamin and mercury. The second factor to be considered is the exceedingly rich lymphatic supply of the mouth and neck. This is important for two reasons; first, the possibility of early, deep-seated metastases, and second, the difficulty which it adds to efficient use of the roentgen ray and radium. Every one is familiar with patients in whom clean excision of a cancer of the mouth associated with persistent postoperative raying of the neck by competent roentgenographers has nevertheless been followed by the early appearance of deep cervical metastases. Since the roentgen ray exerts its influence in limiting cancer metastases by causing proliferation of connective tissues and of the endothelial cells of lymphatics to an extent sufficient to obliterate the lymph channels and tissue spaces, and also by a direct inhibitory effect on the cancer cells, it is obvious that, to a large extent, the richer and the

2. Carson, H. A.: Ancient, War Time and Present Water Supply in Jerusalem, *Engineering News Record* **82**: 1092, 1919.

more deeply situated the lymphatic supply, the less effective will be treatment by the roentgen ray. This tendency of buccal cancer to cervical metastasis has led to the ultraradical, so-called "block dissection" for its cure, which consists in an attempt to remove the cancer and the lymphatic bearing structures of the neck en masse. High morbidity and mortality from infection, and failure to eradicate the tumor by this method, have caused many surgeons to go to the other extreme and to content themselves with local excision with the actual cautery or some form of high frequency current, and ligation of the external carotid artery, thus attempting to minimize recurrence by starving the tumor, and such limitation of metastases in the neck as may be afforded by the roentgen ray. While this method avoids the danger of infection to a large extent, it also fails to cure. Much has been claimed for radium in the treatment of cancer of the tongue; but while its usefulness as an adjunct to other measures is generally admitted, its dependability when applied by present methods to any but the most superficial lesions is yet to be demonstrated. In the management of buccal cancer we are, therefore, brought face to face with the one great, outstanding fact in present-day cancer therapy, namely, the utter necessity of early diagnosis, without which invasion of the rich lymphatic field of the face and neck places an enormous handicap on curative treatment.

FISH AS A FACTOR IN MOSQUITO CONTROL

The attempt to enlist nature on the side of man in combating man's natural foe has been made with great ingenuity in several well known instances. The importation of parasites preying on injurious insects is a familiar example. The value of the dragon-fly as an enemy of the mosquito has been frequently pointed out, although practical utilization of this factor is difficult. Many writers have regarded the activity of fish in devouring mosquito larvae as offering possibilities for more extensive exploitation. Some pertinent observations on this point have recently been published.¹ As the result of work extending over a considerable period, it is concluded that the top minnow (*Gambusia affinis*) is especially suitable for an anti-mosquito campaign because it seeks its food at the surface where the mosquito larvae dwell; is very prolific and viviparous; frequents areas in which mosquito larvae would otherwise thrive, and holds its own in the presence of predaceous fishes, provided it has shallow water for refuge. It is said from first-hand observation to "eliminate the wriggler (i. e., mosquito larva) completely from ponds which are fairly free of protective vegetation and debris." Somewhat similar results were reached by Geiger and Purdy in their observations on experimental mosquito control in rice fields.² The presence of the top minnow meant a considerable reduction in mosquito larvae, especially in the roadside ditches. The authors believe, however,

that under the special conditions obtaining in rice fields the preference shown by the minnow for the deeper, flowing water along levees and their evident avoidance of the midfield make them a doubtful control measure. This should not affect their utilization under favorable conditions.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending July 26, there were 11,065 officers in the Medical Corps, a decrease of 690 from the previous week. The Medical Reserve Corps contained 3,015 officers. The total number of physicians discharged since the beginning of the war is 21,457.

Examination to Fill Vacancies in Regular Army Medical Corps

There exist at this time 600 vacancies in the Medical Corps of the Regular Army. A circular just issued by the Surgeon-General's Office announces the holding of an examination on Aug. 25, 1919, for the purpose of filling these vacancies. Applications will be received up to August 16, but consideration will not be given to those received after that date. A special circular issued by the Surgeon-General's Office states that vacancies will be filled by appointments in the following order:

- Emergency medical officers now in service.
- Members of the Medical Section, Officers' Reserve Corps, who served with credit as officers during the war.
- Former emergency medical officers who served with credit during the war.

It is required that applicants shall be citizens of the United States, between the ages of 22 and 32 years. All persons desiring to apply should address a letter of application for examination to the Adjutant-General of the Army at once, furnishing the following data: Name in full; date and place of birth; permanent home address, medical school or schools from which graduated; professional experience and military service during the emergency, including the organizations in which served and inclusive dates; present organization, if still in the service; grade in which originally appointed; present grade, if still in the service; date, place of discharge and rank at time of discharge, if no longer in the service; also complete statement of any service as a Contract Surgeon; in the Medical Reserve Corps; or in the Medical Section of the Officers' Reserve Corps.

Applications from candidates still in the service should be forwarded to the Adjutant-General through military channels. After a consideration of the applications, selected applicants will be sent letters authorizing them to appear for examination.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

New Wing for Clinic.—The Memorial Laboratory and Clinic for the study and treatment of nephritis, gout and diabetes, founded by the late Dr. Nathaniel Bowditch Potter of New York City, is about to occupy a new wing of the Santa Barbara Hospital, which will be utilized as a complete metabolism unit.

Dr. A. E. Taylor to Deliver Lane Lecture.—The Lane Medical Lectures, which are held biennially at the Stanford University Medical School, will this year be given by Dr. Monzo Engelbert Taylor, professor of physiologic chemistry at the University of Pennsylvania. Dr. Taylor has been representative secretary of agriculture on the War Trade Board for the past two years, and his lectures will deal with the results of his nutritional and medical survey of European food conditions. The exact date has not been definitely decided on, but will be about Dec. 12, 1919.

ILLINOIS

Ricketts Prize Awarded.—The Ricketts prize of \$250, given by the University of Chicago each year to its students for the best research work in bacteriology, was divided between E. B. Fink and F. W. Moulton, both doctors of philosophy.

Poliomyelitis.—Infantile paralysis is said to have appeared in Putnam, Bureau and LaSalle Counties, where several cases have been reported. Dr. Charles E. Crawford has been sent by the state department of health to take charge of the situation.

Cleminson Restored to Practice.—Dr. Haldane Cleminson, Chicago, who recently was paroled from the state penitentiary, Joliet, was reinstated as a practitioner of medicine by the State Department of Registration and Education at its meeting, July 25.

Charge Dismissed.—A charge of practicing medicine without a license, preferred against Chosta Chacomas, Chicago, by Inspector Zuran of the State Department of Registration and Education, was dismissed by Judge Jarecki, July 22, on payment of court costs.

Sanatorium to Open.—The McLean County Tuberculosis Sanatorium will be formally opened, August 17. The principal address will be delivered by Dr. George T. Palmer of the state department of health, and patients will be received in the institution on the following day.

Lecture in Graduate School.—The eighth lecture of the graduate summer quarter in medical science of the University of Illinois was delivered, July 30, by Eben J. Carey, D.Sc., assistant professor of anatomy in the Creighton University Medical School, Omaha, on "The Biomechanics of Primary Bone and Muscle Origin."

Personal.—Dr. Samuel J. Walker, Chicago, who has been for about ten months in Greece and Macedonia in the service of the American Red Cross, returned home, July 24.—Albert H. Koler, Lieut.-Col., M. C. U. S. Army, Evanston, who has been in charge of a hospital train in France, was discharged, July 10.—Dr. Jacob M. Furstman has assumed his duties as health director of Springfield.

Hospital Association to Meet.—A general meeting of the Illinois Hospital Association will be held at the Leland Hotel, Springfield, at 10 a. m., Monday, August 4, under the presidency of Dr. M. L. Harris, Chicago. The object of the meeting is to discuss and take action on numerous matters of vital importance to hospitals in this state, with especial consideration of the needs of the smaller hospitals.

INDIANA

Physician Indicted.—Dr. Frederick W. Krueger, Richmond, was indicted on a charge of manslaughter, following an investigation of his throwing a deformed infant, while still alive, on a city dump two weeks ago. Dr. Krueger said he believed the child was a monstrosity and would have died anyway. His statement to the effect that when he was health officer he had advised other physicians to dispose of deformed children in this manner, prompted an investigation by the grand jury to ascertain if the practice was a common thing among Wayne County physicians. Fifteen physicians appeared before the grand jury. Investigation showed that only one such offense has ever been committed in said county, and this was investigated and an indictment returned. When Dr. Krueger was examining physician of a selective service board, he was forced to resign under pressure of public opinion following alleged pro-German utterances.

Sanatorium Report.—From Sept. 1, 1917, to Dec. 31, 1918, 274 patients were admitted to Sunnyside, the Marion County Tuberculosis Sanatorium at Oaklondon. At the time this report was made, 202 of the patients had been discharged. Statistics show that ninety of the victims were between 20 and 30 years old; fifty-seven were between 30 and 40 years, and thirty-eight were between 11 and 20 years. Home-wives and domestics formed the largest class affected, sixty-two of them being admitted. Skilled and unskilled workmen fell victims alike, forty-six of each being patients. Fifty-one schoolchildren were given treatment.—The Marion County Tuberculosis Association has announced the appointment of a committee, which, in its campaign against disease, will have as its goal the erection of a tuberculosis hospital for receiving advanced cases of the disease. An estimate places the total of tuberculous persons in Marion County between 6,000 and 7,000. For the 300 advanced cases there are now available only twenty-five beds at the Flower Mission. No place is available in the county for the care of the colored patients in the advanced stages of the disease.

KANSAS

Will Erect Building for Medical School.—The building for the Kansas University Medical School for which \$200,000 was appropriated by the recent legislature, will be erected provided the city of Rosedale furnishes the additional ground needed, which is valued at \$60,000.

New Officers.—At a meeting of the Cloud County Medical Association, held in Concordia, July 8, Dr. William B. Newton, Glasco, was elected president; Dr. Frank De Villbiss,

Clyde, vice president; Dr. Leo E. Haughey, Concordia, secretary, and Dr. William F. Sawhill, Concordia, treasurer.

Personal.—Dr. Florence B. Sherbon, Lawrence, has succeeded Dr. Lydia A. DeVilbiss, Topeka, resigned, as head of the child hygiene division of the state health department.—Dr. Charles F. Howe, Atchison, is reported to be critically ill.—Dr. Clarence R. Hepler, health officer of Riley County, has been appointed city health officer of Manhattan.—Dr. George L. A. Hamilton, Kansas City, has volunteered to work for the Red Cross, and sailed for Vladivostok, July 5.—Dr. Orton S. Hubbard, Parsons, superintendent of the State Hospital for Epileptics, has been appointed a member of a commission of forty to make investigations in mental hygiene among the children of the state.—Dr. Harry P. Mere has been reappointed city physician of Abilene.

LOUISIANA

Quarantine Stations for New Orleans.—A measure has been introduced by Congressman O'Connor appropriating \$750,000 for the erection and equipment of a quarantine station at New Orleans.

State Clinic Transferred.—The Louisiana Anti-Tuberculosis League has formally transferred its physical property, consisting of a clinic on Tulane Avenue and Camp Hygieia in St. Tammany Parish, to the Orleans Parish Anti-Tuberculosis League.

Personal.—Dr. W. T. Browne has been appointed district medical officer for the Sixth District Federal Board for Vocational Education which includes the states of Alabama, Mississippi and Louisiana, and Dr. A. W. West has been appointed assistant district medical officer.

Welcome to Service Men.—The Orleans Parish Society, July 8, entertained men who had seen service in the Army and Navy during the war at a welcome home stag held in the Grunewald Hotel. More than 100 physicians were guests of the society and Dr. Paul J. Gelpi, New Orleans, was chairman of the committee of arrangements.

Health Board Loses Test Case.—The Louisiana State Board of Health was unsuccessful in its first attempt to confiscate an alleged illegal shipment of a habit-forming drug into Louisiana because the act is badly framed. Although its purpose is mainly penal, no penalty maximum and minimum is provided. This decision dissolved a writ of sequestration issued against a quantity of morphin said to have been shipped by a drug company of St. Louis to a pharmacist in New Orleans.

Hospitals to Be Erected.—Plans for the John Dibert Tuberculosis Hospital, New Orleans, were approved by the board of trustees, July 5. The hospital will be located at Carrollton and Tulane Avenues, on property purchased by the city. The building will be of brick, three stories in height and will accommodate 162 patients. The hospital has been made possible through the generosity of Mrs. John Dibert.—It has been decided by the board of administration of the Charity Hospital, New Orleans, to erect an electric power house for the institution at the cost of about \$90,000.—The city board of Broekhaven has agreed to provide \$25,000 in bonds for the establishment of a Methodist hospital in that city on a site donated by Mr. S. E. Morton.—Drs. Dave B. Davis, Edward G. Sewell, A. Marshall Jaas and Edgar S. Matthews, Bunkie, have announced their intention of erecting and conducting a sanatorium capable of caring for the needs of the surrounding country.—The third branch of the New Orleans Lying-In Hospital was opened, June 15. It is located in Ursuline Street.

MARYLAND

Personal.—Dr. Henry A. Naylor of Pikesville, who recently returned to his home after serving with the Medical Corps, U. S. Army, has been appointed sanitary officer for the third district of Baltimore County, a position which he held before entering the service.

Typhus Fever Reported.—The first case of typhus fever to be reported to the health department in several years was brought to the attention of Health Commissioner John D. Blake, Baltimore, and the patient, a woman, 50 years of age was immediately sent to quarantine. In an investigation to determine the cause of typhus fever, Dr. C. Hampson Jones, Baltimore, chief of the state bureau of communicable diseases, requested the assistance of the U. S. Public Health Service and Surg. Arthur M. Stimson, with one of his laboratory assistants, came to Baltimore and took blood cul-

tures of the patient, while Surg. Joseph Goldberger investigated the case and confirmed the diagnosis.

Nurse Shortage Grave.—There is a serious shortage of nurses in Baltimore. Hospitals are beginning to feel the pinching effects of a lack of enthusiasm on the part of young women for a profession that always has been held as the highest a woman could enter. One of the direct and most serious effects of the situation is that no attempts at expansion can be made by the hospitals, because no nursing forces are available. More space, more buildings and more beds are a necessity in Baltimore at this time because the number of patients seeking admission to the hospitals is greater than it has been for many years. Virtually all the hospitals are crowded to capacity, and the patients are being turned away. It is estimated that 150 trained nurses could be placed in hospital positions immediately. It is hoped that the return to normal civilian life of hundreds of Baltimore young women who have been engaged in war work may go far toward relieving the present shortage of nurses.

Typhoid Fever in Baltimore Annex.—For the first six months of 1919, the new annex of Baltimore city showed a big lead on the old city in the morbidity rate from typhoid fever, according to a statement prepared by Dr. William T. Howard, assistant commissioner of health, for the purpose of showing the necessity for an adequate supply of filtered water in the new territory. Many small communities outside the original twenty-four wards get their water from wells and the health department has closed several, because of pollution. The morbidity per hundred thousand population for the first six months of 1919 for the old twenty-four wards was at the rate of 21.49 per annum, in comparison with 27.01 for 1918, while in the annex for the first six months of 1919 the typhoid morbidity was at the rate of 102.5 per annum. Therefore, the morbidity rate for typhoid fever for the first six months of 1919 was nearly six times greater in the annex than in the original twenty-four wards of the city. On account of the very high incidence of typhoid fever in the annex territory, the typhoid fever rate for the whole of Baltimore for 1919 promises to show a decided increase over 1918, the morbidity rate being already for the six months nearly one third greater than the rate in 1918.

MISSOURI

Teaching Center for Nurses.—The St. Louis Chapter of the American Red Cross has completed arrangements for conducting a teaching center for public health nurses in St. Louis. An area in the congested district in the southern portion of the city has been mapped out and a large building on South Broadway, formerly occupied by a saloon, has been rented for the clinic center. Miss Welch, formerly instructor in public health nursing at the Henry Street Center in New York, has been engaged and placed in charge of the practical work. It is the purpose of this teaching center to supply nurses trained in public health work for community service in the southwestern states. Information regarding the courses can be obtained through the Southwestern Division of the American Red Cross, or at the St. Louis Chapter, Frisco Building.

Former Medical Officers Organize.—July 9, an organization composed of ex-medical officers, U. S. Army, residing in southwest Missouri, was perfected at Springfield. Dr. William A. Delzell, Springfield, was temporary chairman. About forty men were present from the following counties: Vernon, Barton, Jasper, Newton, McDonald, Barry, Lawrence, Stone, Dale, Cedar, St. Clair, Hickory, Polk, Christian, Taney, Webster, Dallas, Camden, Laclede, Wright, Howell, Oregon, Texas, Pulaski and Greene. The temporary committee on organization, composed of Drs. James E. Dewey, J. LeRoy Atherton and Otto C. Horst, all of Springfield, was made a permanent committee to complete a constitution to be submitted at the next annual meeting. It was voted that the first meeting be held at Joplin, November 11, the anniversary of the signing of the armistice. The following officers were elected: president, Dr. William A. Delzell, Springfield; vice president, Dr. Louis M. Edens, Calhoun; secretary, Dr. Horace A. Lowe, Springfield; treasurer, Dr. James H. Fulbright, Springfield; corresponding secretary for Jasper County, Dr. Robert M. James, Joplin.

NEBRASKA

Microscope Stolen. Dr. Sydney S. Wilson, Nebraska City, announces that a Bausch & Lomb microscope, valued at \$125, has been stolen from his office. He also states that a few days prior to the stealing of his microscope, a microscope was stolen from a physician's office in Pawnee City.

Medical Arts Building.—The Medical Arts Building, to be occupied by physicians' offices, which is about to be erected in Omaha, is being constructed by two department stores. Physicians are being solicited to buy stock in the undertaking. The sixteenth floor of the building will be occupied by the Omaha-Douglas County Medical Society and the seventeenth floor will contain rest and lounging and dining rooms.

Personal.—Dr. Benjamin F. Williams, Lincoln, received his discharge from the United States service, June 30, and immediately assumed his position as a member of the state board as commissioner of state institutions. —Dr. Arthur C. Stokes, Omaha, who organized Base Hospital No. 49, and who recently returned from overseas, has been cited by General Pershing for meritorious service. —Dr. Varro M. Boal, after more than thirty-five years of practice at Aulurn, has disposed of his practice and will move to California. —Dr. Roy A. Dodge, Omaha, has been elected grand chancellor of the Knights of Pythias.

Hospital Notes.—A campaign for a general hospital for Nebraska City and Otoe County has been inaugurated. —Plans for the Good Samaritan Hospital at Kearney have been approved. The building is to cost about \$125,000. —Plans are being prepared for the new Lord Lister Hospital, Omaha, to be erected at Twenty-Sixth and Dewey Streets by Dr. Edwin C. Henry. The building will be six stories and a basement in height, will cost more than a quarter of a million dollars and will have capacity for 140 patients. —The Order of the Eastern Star of Nebraska has purchased a 10-acre tract of land north of Fremont on which a hospital will be erected at a cost of \$150,000, to be used in connection with the Masonic Orphanage. —Three registered nurses have closed a deal for the purchase of the G. O. Burns residence at Columbus, which they will convert into the Columbus General Hospital. —A site has been purchased in Ainsworth for the Brown County Hospital.

NEW JERSEY

New Health Officers Organized.—Organization of the Health Officers' Association of Essex County was effected at Newark, July 7. —Dr. Charles V. Craster, Newark, was elected president and William B. Palmer, milk inspector of the Oranges, secretary.

Personal.—Dr. Elfre G. Graff, Somerville, who has been assistant physician at Vassar College for several years, has sailed for Turkey where she will be assigned to work among Armenian women. —Dr. Charles B. Sitgreaves, Pennington, has resigned as medical superintendent of the Burlington County Tuberculosis Sanitarium, New Lisbon.

New Wing for Hospital.—With simple ceremonies the new wing of the Monmouth Memorial Hospital, Long Branch, erected by Mr. and Mrs. Charles A. Wimpfheimer, New York City, in memory of their son, Jacques Wimpfheimer, who died in the military service a year ago, was dedicated, July 19. The new building has cost \$150,000 and was presented to the board of governors by former Ambassador Abraham I. Elkus and accepted for the hospital by its president, Mrs. William B. Harper. The new wing doubles the capacity of the hospital.

NEW YORK

Smallpox Follows Small Circus.—A communication from the Pennsylvania to the New York State Department of Health, it is said, reports that cases of smallpox have appeared in the wake of the Spark's circus which has been traveling through Virginia, Maryland and Pennsylvania, and was last heard of in Ohio.

Public Health Association Organized.—At a reunion of the health officers who have taken the course for health officers at Syracuse University under the direction of Sanitary Supervisor Frederick W. Sears, M.D., the Central New York Public Health Association was organized with an initial charter membership of sixty-two.

Personal.—Dr. Carl R. Comstock, Saratoga Springs, who has just returned after two years' service in the Army, has been appointed instructor in diseases of the heart in the Albany Medical College. —Fred M. Meader, Major, M. C., U. S. Army, Albany, director of the division of communicable diseases, state board of health, has returned from France and has resumed his position.

Tuberculosis Clinics in Albany.—The state department of health has inaugurated a series of eight tuberculosis clinics in Albany. The first was held, July 29, and the last will be given, August 8. These clinics are open to individuals

not under the care of a physician or who are referred by a family physician and who have had influenza followed by a persistent cough with other significant symptoms.

More Public Health Nurses to Be Employed.—The Essex County Chapter of the American Red Cross has voted to employ a public health nurse.—Wheatland, Livingston County, has appointed a community nurse.—Appropriations for public health nurses have also been made at Fort Plain and St. Johnsville.—Mount Morris is to have the services of a community nurse and Madison County has recently appointed a tuberculosis nurse.

State to Care for Tuberculous Men.—According to an announcement recently made by the tuberculosis committee of the State Charities Aid Association, of the men called to military service in New York state, outside of the city of New York, 3,411 were rejected by the local draft boards because of tuberculosis. The names, but not the addresses of these men, have just become available and steps are being taken by the association, in conjunction with the state department of health, for placing them under the care of local health authorities and tuberculosis societies.

Cooperation of Volunteer Health Organizations Requested.—In order to secure the maximum cooperation between existing health agencies, the state health department is desirous of securing an up-to-date list of all organizations working for public health in any of its various divisions. Reports and regular publication of these organizations are solicited and in return the state department of health will be glad to send such publications as may be requested. It is particularly desired that the state health department should be kept informed of new exhibit material, posters, panels, lantern slides, films, etc., in order that exhibit work may be coordinated.

New York City

Doctors and Nurses Sail for Serbia.—A party of twenty doctors and nurses sent by the Serbian Relief Committee of America sailed, July 26, on the *President Wilson* for Patras and thence to Saloniki. The party is under the direction of Dr. Barton W. Brush, U. S. Navy, Flushing, N. Y.

Jacobi Memorial Hospital.—A campaign committee has made plans for raising funds for the erection of an Abraham Jacobi Memorial Hospital for the Washington Heights section. This locality has been chosen because of its lack of hospital facilities. The active campaign will not be begun until November. Dr. S. Robert Schultz is executive director of the campaign and has issued a call for volunteer workers. A resolution will be introduced in the board of aldermen at the first fall meeting, proclaiming Heights Hospital Week from November 15 to 22.

Foundation for Destitute Children.—The will of Mrs. Rosa E. Spang makes a bequest estimated at more than \$1,000,000 for the relief of the poverty and distress of children and babes who are in want through abandonment or the death of their parents. Former Atty.-Gen. George W. Wickersham, Col. Michael Friedsam and Dr. Henry Dwight Chapin are named as directors and executors of the fund. The will provides that the foundation shall be known as the Rosa Spang Foundation and that its chief work shall be to select children sent to orphanages and homes and make provision for their education and instruction.

Asks War Hospital to Keep Personnel.—A report on the war work of Base Hospital No. 8, prepared for the trustees of the institution by Dr. Charles Gordon Heyd, contains a communication from Surgeon-General Ireland commending the work of the unit and asking that the personnel be kept intact so as to be prepared for work in case of future emergencies. The hospital was opened in the village of Savenay, France, in August, 1917, with 127 beds. At the time of the signing of the armistice the bed capacity was 18,000. The commanding officer was Lieut.-Col. Joseph F. Siler, the director of surgery, Major Samuel Lloyd and the director of medicine, Major R. Julian Estill.

Personal.—Dr. Nelson W. Janney, formerly chief of the medical services of Base Hospital No. 99, American Expeditionary Forces, has resigned his professorship in the New York Post-Graduate Hospital to succeed the late Dr. Nathaniel Bowditch Potter in the directorship of the Memorial Laboratory and Clinic for the Study and treatment of Nephritis, Gout and Diabetes, Santa Barbara, Calif.—Mr. Howard Fonda has returned to his position in the department of bacteriology in the Long Island College Hospital, Brooklyn, after eighteen months' service in France.—Dr. Calvin Brewster Coulter has begun his duties as assistant

professor of pathology in the Hoagland Laboratories.—Dr. Carl H. Laws, Brooklyn, has been elected president of the Clinical Society of the Long Island College Hospital.—Phillip Moon Stimson, Capt., M. C., U. S. Army, who was severely wounded by shrapnel near Ypres, and for nearly a year has been adjutant of American Red Cross Military Hospital No. 2, Paris, has received a citation from General Pershing for "exceptionally meritorious and conspicuous service."—Dr. Charles Theodore Graham-Rogers, who served during the war as a line officer with the 27th Division, has been appointed captain, M. C., N. Y. N. G., and is attached to the 47th Infantry.

Economic Conditions Create Health Problems.—The bureau of preventable diseases of the New York City Health Department, under the direction of Dr. Louis I. Harris, has just made public the results of a pioneer investigation into some of the medical aspects of the high cost of living. An investigation of the living conditions of 2,084 families visited by public health nurses, primarily for the purpose of supervising cases of tuberculosis, diphtheria and scarlet fever, forms the basis of this report. The families consisted of 4,991 adults and 5,612 children, an average of 508 persons and 269 children per family. It is believed that these families represent a fairly typical cross-section of conditions in New York City. Of these families 51 per cent. had a total income not exceeding \$900 a year and a total of 72 per cent. had an income not exceeding \$1,200 a year. A study of the increased cost of living on the normal dietary of the families showed that in 37 per cent. of these families meat was entirely eliminated; in a slightly larger percentage eggs were entirely eliminated. In 293 families the use of bottled milk was given up; in 71 per cent. of the families the amount of milk consumed by the children was considerably reduced. In 370 families the use of butter was eliminated and sugar was omitted from the dietary of children in seventy-one of these families. In these families the effect of these conditions of daily life on sickness and on the period of convalescence was studied. It was found that in 287 cases out of a total of 2,183 cases of illness, or in a little over 13 per cent., recovery was definitely retarded because of the increased cost of the essentials of life.

Health Department Has Legal Right to Treat Drug Addiction.—The health commissioner has received an opinion from Corporation Counsel William P. Burr supporting Dr. Royal S. Copeland's position that drug addiction should be considered a disease to be dealt with by the health department and not a criminal condition calling for punishment in penal institutions. He holds that there is no legal bar to prevent the use of the city's farm at Warwick, N. Y., as a colony for the treatment of drug addiction. Corporation Counsel Burr's opinion holds that the facts disclosed by the Mayor's Public Welfare Committee, which was created by him in the interest of public health, morals and safety to investigate the evil of drug addiction in this city, are most alarming. The records of recent trials in the federal courts in this district show the close connection between the dishonest druggists and physicians, it having been ascertained that eight physicians recently arrested for illegally practicing in this traffic between them wrote more than 1,500,000 narcotic drug prescriptions in less than one year's time. Dr. Copeland declares that he has doled out 167,000 grams of morphin and heroin to addicts within seven days. Dr. Walter R. Herrick, commissioner of the state department of narcotic drug control, says that there are three things that must be done before the disease of drug addiction can be eliminated, namely, drug smuggling and peddling must be stopped, the manufacture and importation of heroin must be prohibited, and there must be a national registration of drug addicts. The corporation counsel also expresses the opinion that there is no legal reason why the health department is not free to accept the offer of the Rockefeller War Demonstration Hospital.

OHIO

Night Clinics Inaugurated.—Night clinics have been established in Cincinnati at all public health stations, every Friday night from 7 to 10 p. m. At the Sands School, Cincinnati, this clinic is being held every Thursday from 7 to 10.

Personal.—Dr. Gertrude E. Sturges, Mansfield, who has been in service in Italy, arrived in New York, July 5.—Frank W. Hendley, Major, M. C., U. S. Army, Cincinnati, who has just returned from Army service, has been added to the staff of the public health stations of the city.

Typhoid Fever.—Eight of the five larger cities of Ohio had a typhoid death rate last year of less than 10 to 100,000 of

population but for the state at large the 1918 rate was nearly 15 deaths for 100,000 population. The reports for 1919, thus far, indicate a typhoid prevalence much below normal.

Health Supervisors Appointed.—The state department of health has announced the appointment of the following district health supervisors: Dr. Carroll H. Skeen, Greenfield; Percy K. Holmes, Delaware; Walter S. Bennett, Cardington; Jackson A. Frank, Columbus; Charles R. Deeds, Fresno, and Henry E. Cock, Cincinnati. Two other appointments will be announced later. The first work of the supervisor will be to promote the reorganization of the local health administrative changes of the state in accordance with the Hughes Act.

Health Propaganda.—The state department of health has prepared an exhibit which it plans to install at eleven county fairs. The dates thus far arranged are: at Wellston, July 22 to 25; at Athens, August 19 to 22, and at Logan, September 24 to 27. The exhibit will be in service continuously until October 18. The care of babies, sex hygiene and venereal disease control are to be emphasized in displays, and the exhibit is accompanied by a lecturer and a nurse. A venereal disease clinic has been opened at Ashland, which is the eighteenth Ohio city to be equipped with such clinical facilities. The clinic will be maintained jointly by the city, state and federal governments.

PENNSYLVANIA

Mosquito Bill Vetoed.—Governor Sproul has vetoed the bill providing a method of getting rid of mosquito breeding places, saying it would make a radical innovation in the assessment laws of the state.

State Appropriations.—The following shows the appropriations made by the last legislature to the state institutions, sanatoriums, hospitals and semistate institutions:

	Appropriated	Approved
State institutions	\$13,400,073	\$13,315,073
Semi-State institutions	2,005,500	2,005,500
Hospitals	6,343,300	6,227,900
Sanatoriums	2,230,595	2,239,595

New Lehigh Valley Officers.—At the annual meeting of the Lehigh Valley Medical Association held at the Delaware Watergap, July 24, the following officers were elected: president, Dr. Jacob A. Trexler, Lehigh; vice presidents, Dr. Samuel P. Mengel, Wilkes-Barre; Harry C. Fisler, Easton; Frederick A. Fetherolf, Allentown, and James M. Reese, Phillipsburg, N. J.; secretary, Dr. Alexander Armstrong, White Haven (re-elected); assistant secretary, Dr. Roger P. Batchelor, Palmerton (re-elected), and treasurer, Dr. David H. Keller, Bangor (re-elected).

Special Training Bill Passed.—The Lanius bill, which provides for the handicapped children in the public schools, has been signed by Governor Sproul. The measure is an amendment to the school code, and was drawn by the Public Charities Association. Mental and medical clinics are provided to ascertain the children who are tuberculous and need open-air school treatment; children who because of defects in sight or hearing need special training, as well as the children who are incorrigible or who are retarded because of weak intellects. Dr. Thomas E. Finegan, state superintendent of public instruction, worked the general plan out. It is estimated that out of the 1,500,000 children now in the public schools, one tenth, or 150,000 would be reportable, because of either physical or mental defects. Out of this 150,000 only 15,000 could be classed as feebleminded, or 1 per cent. of the entire school population.

Philadelphia

Indict Licenseless Physicians.—William J. Looker and Philip S. Dailey were indicted, July 24, charged with practicing medicine without a license.

Health Director Warns of Epidemic. Dr. Wilmer Krusen, director of Public Health and Charities, has issued a warning to the public to keep roofs intact and keep water out of cellars in order to prevent a wave of sickness following nine days of rain.

Expect Hospital Merger.—The Women's Medical College and Hospital and the Woman's Hospital of Philadelphia will soon be merged. With the opening of the fall term at the college, definite steps to unite the interest of the college and hospital are expected to be taken.

Prohibition Hits Hospitals. William D. McAllister, superintendent of "Blockley," states that admissions from July 1 to 15, were one half as large as for the same period last year. Superintendent McAllister said that the number of

inmates of the women's almshouse department at Blockley and in the men's department at Holmesburg is the lowest it has been for some time. There are 811 men and 631 women. Rum and social disease are stated to be responsible for 70 per cent. of the admissions to the almshouses.

Infant Mortality Drops.—Infant mortality in Philadelphia for the first six months of 1919 dropped 23.31 per thousand compared with the death rate of 1918, according to a statement issued by Director of Health and Charities Krusen. During the first six months of this year, 1,838 babies, under the age of 1 year, died, a mortality rate of 85.69 per thousand, compared with 2,338 death in 1918, a rate of 109.0, and 2,159 deaths in 1917, a rate of 100.65. The decrease is due to the work of the Division of Child Hygiene, and this division has mapped out an extensive campaign of child conservation.

Insanitary Soda.—Dr. Wilmer Krusen, director of public health and charities, has issued a statement on cleaning up the soda fountains. Dr. Krusen states that the most fertile source of disease and disease dissemination lies in the unclean drinking glass. Improperly cleansed glasses used at the soda fountain may be responsible for the spread of tuberculosis, typhoid, diphtheria, sore throat, infectious colds and diarrheal diseases. Ordinary rinsing does not clean the glass from a health standpoint. It requires boiling water with soap or a suitable disinfecting solution to make them safe for reuse. When this cannot be done it is better to use the individual cup which can be destroyed. Soda fountain dealers who use dangerous dyestuffs and artificial sweetening, it is declared, should be closed on trial before the public.

CANADA

Decrease in Smallpox.—There has been a marked decrease in smallpox cases in Halifax, N. S., during the past two weeks, and there are now only fifteen patients at the hospital. The paratyphoid epidemic has also died out.

Personal.—Dr. W. P. Eakins, Montreal, who has been overseas several years, has accepted an appointment as professor of therapeutics at Edinburgh University. Dr. Harris C. Mersereau, Notre Dame de Grace, Quebec, has returned from overseas.

Limit Liquor Prescriptions.—The Medical Council of British Columbia has passed a resolution to the effect that the liquor prescriptions of practitioners shall not exceed 100 per month, and this resolution has been forwarded to the minister of education.

Military Medical Services.—At the annual meeting of the Canadian Medical Association in Quebec, in June, a special committee was appointed to deal with a resolution unanimously passed with regard to the Military Medical Services of Canada. The resolution was proposed by Dr. Herbert A. Bruce, Toronto, and seconded by Dr. George E. Armstrong, Montreal. It provides for the teaching, in the medical schools, of the medical history of the great war, the reorganization of the Canadian Army Medical Corps, so that full advantage may be taken of modern scientific knowledge of medicine; and that the rate of pay in the service may be advanced to that prevailing in the Royal Army Medical Corps.

University News.—The University of Toronto has authorized a new degree for those wishing to specialize in the different branches of medical research—B Sc. (Med.)—Bachelor of Science in Medicine. It will be given to students who, on the completion of the first three years of the six years' course, obtain honor standing and proceed to one year in research work. The University Hospital Supply Association of Toronto has held its last meeting. During the four years of war \$121,107.25 was raised, and \$117,007.21 disbursed. The grand total of surgical articles sent overseas numbered 1,808,257. The balance of \$4,100 left in the treasury was divided between Pearson Hall for blind soldiers, Toronto, and the Orthopedic Hospital.

Hospital News.—The government of Ontario is not in a position to confirm recent rumors that the Ontario military hospital at Orpington, England, has been sold to English capitalists. If it is not sold, the full equipment will be brought back to Canada and used in the provincial institutions of Ontario. The Provincial Hospital for the Insane in Toronto is rapidly being evacuated of patients, and they are daily being removed to the Whitby institution, which has been handed back to the government by the military authorities. There are yet about 1,000 patients in residence, and it will take two months to effect their removal. Toronto is to have a brand new reception hospital. It will cost about

\$84,000, and will have accommodations for sixty patients. It is understood that a site has been selected in the northwest-ern section of the city.—Dr. Elizabeth Kilpatrick, assistant physician at the Northampton State Hospital, Northampton, Mass., has been appointed an assistant physician in charge of the women's wards of the Nova Scotia Provincial Hospital.—The federal government has granted \$62,500 to the St. John (N. B.) General Hospital. The sum goes to defraying the expenses in connection with sick mariners, and will provide for twenty-five beds on a basis of \$2,500 each.

GENERAL

Physical Reconstruction Treatment.—July 1, 25,000 officers and enlisted men of the army were undergoing treatment in twenty hospitals equipped for physical reconstruction work. These patients will be obliged to remain under treatment from two to four months.

Tristate District Society Meeting.—The annual meeting of the Tristate District Medical Society will be held in Rockford, Ill., September 1 to 4. Elaborate plans are being made for the entertainment of the visitors by the Winnebago County Medical Society, of which Dr. John E. Tuitt, Rockford, is president.

Reduction of Army Patients.—Between May 31 and June 21 the number of patients in the army hospitals decreased from 50,387 to 42,648 and on the latter date there were 21,261 vacant beds in the hospitals. During June, fifteen hospitals with a capacity of 12,959 beds were closed, and during July, seven hospitals were closed.

Personal.—By a vote of 9 to 7, July 25, the senate military committee ordered a favorable report on the appointment of Lieut.-Col. Robert E. Noble to the permanent rank of Brigadier-General, Medical Corps.—John H. C. Scudder, Major, M. C., U. S. Army, who went to Siberia in command of Field Hospital and Ambulance Company No. 4, was the first acting surgeon-general of the Philippine National Guard and organized the medical department in the Philippine Islands.

Bill for Retired Army Nurses.—The Senate Committee on Military Affairs has made a favorable report to the senate on Senate Bill 2496, introduced by Senator James W. Wadsworth, Jr., of New York, authorizing the retirement of members of the Army Nurse Corps who have had twenty years' active service. The bill provides that the nurses shall receive 75 per cent. of their active pay, exclusive of foreign service pay. The committee recommends passage and it seems to be assured that the measure will pass.

Motor Clinic.—An automobile truck known as the "Child's Welfare Special" has been put into the field by the Children's Bureau of the United States Department of Labor to test the usefulness of the automobile in carrying the message of better babies into the rural communities. The truck is completely fitted as a model baby clinic and has a government physician and nurses in charge to examine children and give the mothers advice concerning the care necessary to make and keep the babies well.

Army Roentgen-Ray Work.—The training of officers and enlisted men of the Medical Corps of the Army in roentgen-ray work will soon be concentrated at the Army Medical School, Washington, D. C., under the section of roentgenology of the Office of the Surgeon-General. Henry C. Pillsbury, Lieut.-Col., M. C., is to be appointed professor of roentgenology at the school. A class of eighteen began the three months' course, July 1, and on graduation these officers will be eligible for assignment to duty in the roentgen-ray department in any military hospital.

Appropriation by Congress for Investigation and Combating Influenza.—Four measures appropriating funds and authorizing the United States Public Health Service to investigate and combat a recurrence of the influenza epidemic are now before congress. Senator Warren G. Harding of Ohio has introduced a joint resolution appropriating \$5,000,000 for an investigation of influenza and pneumonia. His measure cites that the recent influenza epidemic caused 350,000 deaths in the United States. The Public Health Service and research institutions are authorized to make this investigation. A bill introduced in the House by Congressman Simon D. Fess of Ohio, authorizes the Public Health Service and the medical departments of both the Army and the Navy to investigate and combat the disease and appropriates \$1,500,000 for this purpose. Congressman William W. Larsen of Georgia and Congressman Black of Texas have introduced similar bills for making an investigation of influenza and allied subjects. The Larsen and Black measures carry an

appropriation of \$500,000 each. All four measures charge the United States Public Health Service with carrying out the provisions of the act, although cooperation with the army and navy medical departments is advised.

Infant Mortality Rates in the United States.—The New York Milk Commission has recently issued a report on the infant mortality rates of the different cities of the United States for the year 1918. This report shows that the infant death rate for New York City was 92 per thousand living births. Although the estimates show that the death rate for the country increased seven points last year, the milk commission believes these rates are remarkably low when all the elements conspiring against the baby are considered. The infant mortality rate for seventy-nine cities with populations under 50,000 was 97.2. The rate for thirty-eight cities of between 50,000 and 100,000 was 113.8, and that for forty-five cities of 100,000 population was 103.5. The average baby death rate for the registration area of the United States is 104. Twenty-two of the cities of 100,000 are above this average, and twenty-two are below. The rates for a number of the larger cities are reported as follows:

Chicago, 104.3; Philadelphia, 126; Boston, 114.9; Baltimore, 147.8; Pittsburgh, 125.3; Buffalo, 121.5; Milwaukee, 108.2; Cincinnati, 104.1; Newark, N. J., 104.7; New Orleans, 124.3; Washington, D. C., 110.4; Jersey City, 118.7; Louisville, Ky., 117.3; Denver, 107.3; Syracuse, N. Y., 117.4; Birmingham, Ala., 133.5; Memphis, Tenn., 145.1; Scranton, Pa., 144.3; Richmond, Va., 146.3; Fall River, 161.3; Lowell, Mass., 159.1; Albany N. Y., 107.4. Only three cities reported baby death rates below 50. These cities are all of the class below 50,000. Brockton, Mass., has the lowest rate, 35.4; Madison, Wis., is next with 38.1, and Pasadena, Calif., third, with 43.8.

FOREIGN

Physician Wounded by Maniac.—An inmate of the asylum for the insane at Alessandria recently severely wounded Dr. L. Gualino, the physician in charge. One of the wounds is in the thorax and the prognosis is grave. The same maniac ten years ago tried to kill another man, and in 1914 nearly strangled the physician in charge at that time, Professor Frigerio.

Belgian Conference to Discuss Professional Matters.—The sixteenth Congrès de médecine professionnelle was held last week at Antwerp under the auspices of the Fédération médicale belge. The main topics up for discussion were contract medicine; dentistry and physicians; organization of cooperative purchasing and medical printing and medical cooperative work in general.

Raising Medical Fees in Paris.—The Syndicat des médecins de la Seine, the representative association of the medical profession in the Seine district for other than strictly scientific purposes, has issued a notice to the general public of Paris stating that henceforth medical fees are to be increased to just twice the fees current before the war. Professional calls demanded after 7 p. m. and on Sunday will be charged for at double rates, and when the physician is summoned between 9 p. m. and 7 a. m. the rate will be tripled.

Deaths in the Profession Abroad.—Dr. L. Bonaventura of Rome succumbed recently to typhus contracted in medical services to Austrian prisoners of war doing agricultural work.—The cable reports the death of Emil Fischer, professor of chemistry at the University of Berlin and chief of its Chemistry Institute, aged 67. He was given the Nobel prize in chemistry in 1902 for his research on sugars, synthesis of albumin, polypeptides, etc. He also received the Becholtz medal in 1909, and the Franklin Institute of Philadelphia awarded him the Elhott Cresson gold medal in 1913.

The Paris Child Welfare Institution.—The Institut de puériculture de la Faculté de médecine de Paris was formally inaugurated, July 1, with much ceremony. The first million francs for it was offered by the American Red Cross and this was doubled by another million donated by French philanthropists. Professor Roger, dean of the Paris faculty, expressed the gratitude of the French and spoke in particular of the penny contributions of the children of America, their contribution to the work totaling 500,000 francs. He urged that a similar *Oeuvre du sou* be started in France. A society was organized at the same time, the Société de l'Institut de puériculture, and the constitution and by-laws adopted.

Italian Newspaper's Sanatorium.—The *Giornale d'Italia* opened a subscription list for a sanatorium for the children of soldiers. Large sums were collected, and the newspaper was tendered the use of a sanatorium for crippled children

that had been founded on a large scale as a memorial to the son of the Princess Chigi, killed early in the war. The sanatorium has extensive grounds, on a lake, near Ariccia, and was modeled on the most approved plans. The combination of the two enterprises has resulted in a model institution of the highest grade, it is said, with accommodations to date for 120 children. The issue of the *Italia Sanitaria* for June 25 is devoted almost entirely to an illustrated description of it.

Congress for Medical Radiology.—The second annual meeting of the Società Italiana di Radiologia Medica is to convene at Genoa, Oct. 20, 1919. There is to be an exhibition in connection open to exhibitors of the allied nations. The subjects appointed for discussion are the biophysical bases of radiotherapy, and the radiologic picture of pulmonary tuberculosis. The congress is to be open to physicians, biologists, physicists, designers and technicians interested in the scientific and practical development of medical radiology. The subscription fee is 10 lire (\$2) for persons not members of the society. For information address the secretary of the congress, Dr. G. Pesci, Ospedale Pammatone, Genoa, Italy.

Red Cross Activities.—In a report of the Bureau of Hospital Administrations of the American Red Cross, prepared for the War Department, it is shown that during the war the Red Cross furnished more than 1,110,000 days of hospital care for the American soldiers, and admitted to its hospitals a total of 89,539 patients. At the cessation of hostilities, the organization had in operation twenty-two military hospitals with 14,326 beds. In addition to this, assistance of many kinds was extended by the bureau to 2,800 French hospitals. During the last nine months of 1918, the Red Cross delivered more than 64,000,000 dressings, pads, sponges and bandages, and nearly one and one-half million splints and accessories. During the influenza epidemic the work rooms of the Red Cross in Paris made and delivered more than 600,000 influenza masks to the American troops.

LATIN AMERICA

Drugstores in Cuba.—The last report of the Department of Sanidad y Beneficencia of Cuba shows that at the beginning of the year 1919 there were in Cuba 958 drug stores.

Physician Appointed Consul from Colombia at Baltimore.—The *Repertorio de Medicina y Cirugía* of Bogotá mentions that Dr. Daniel Molano has been appointed consul ad honorem for the Republic of Colombia in the city of Baltimore.

Personal.—Dr. M. Escudero Vargas, physician in charge of the hospital at Iquique, Chile, has been designated by the government of that country to make a study in the United States of matters relating to infant surgery and children's hospitals.

Death of Dr. Hernández.—It is reported from Caracas that Dr. José G. Hernández, one of the most prominent physicians of Venezuela, also a scientist of note, was killed there, June 30, in an automobile accident. A period of public mourning has been declared.

Influenza in Rio de Janeiro.—A recent report of the Department of Public Health of Rio de Janeiro shows that influenza caused a total of 12,720 deaths in that city during the year 1918. The epidemic reached its crest in October, when the deaths rose to 8,817 from 48 the previous month of September. In November the deaths amounted to 3,287, decreasing to 284 in December. The mortality was nearly equally divided among the sexes in the Brazilian native population, namely, 5,319 males and 5,329 females. Among the foreigners, the proportion was naturally heavier among the males who predominate in numbers. Next to influenza, tuberculosis caused most deaths during the year, namely, 4,909. During the year the estimated population of Rio de Janeiro decreased from 911,721 in January to 875,477 in December. The total number of deaths was 35,113, the mortality rising from an average of 1,700 during the first eight months of the year to an average of 6,524 for the last three months.

Blindness in Mexico. The subject of blindness in Mexico has lately been attracting much attention in that country. Dr. José Joaquín Lozano has recently published a study of the prevalence of blindness and its distribution and causes. It seems that in the eighteenth century blindness was very rare in Mexico. According to the last censuses, in 1900 the proportion of blind was 95.2 per 100,000 and in 1910 of 78.2, the last figures being probably more correct. Blindness is proportionally more prevalent in the north of the country, this condition being less prevalent in the lower and warmer regions near the seashore. Judging from the records of the National School for Blind People, smallpox was the most

frequent cause of blindness during the first years (1870-1879) of the foundation of the school. Ophthalmia neonatorum, which at the beginning caused 30 per cent. of the blindness, has been increasing gradually until in the period of 1910-1914 was responsible for 75.6 per cent. of all cases. The cases due to smallpox have also been increasing during the last eight years probably due to the neglect in the enforcement of vaccination. All the data available seem to indicate that trachoma is very rare in Mexico, contrary to the opinion prevailing abroad.

PARIS LETTER

PARIS, July 3, 1919.

The Smallpox Record in Paris from August, 1914, to June, 1919

At a recent meeting of the Academy of Medicine, Dr. R. Wurtz, hospital physician and university professor at the Paris School of Medicine, reported that there had recently been in Paris an epidemic of smallpox which had awakened some anxiety. There were, it seems, fifteen cases during the month of April, and twenty-two cases during May. This is all the more regrettable because, from the beginning of the war until March, 1918, the mixed assemblage of people in Paris had enjoyed almost absolute immunity. Thus, there were only six cases recorded in 1914; seven in 1915; four in 1916; six in 1917; fifty-five in 1918, and forty-seven during the first five months of 1919. During the war the various public services were untiring in their efforts to prevent a smallpox epidemic. The high degree of frequency of positive vaccinations has been noted; for example, 98 per cent. being successful in the case of an agglomeration of 3,000 employees.

The reappearance of smallpox is due, in part, to foreign importation from such countries as Morocco, Spain, Italy and Algeria; in part to the violation of sanitary regulations, particularly as regards crossing from North Africa to France, and in part to the obstinate refusal, on the part of the public, to be vaccinated. More than 60 per cent. of the hospitalized patients had refused revaccination since childhood.

An Appeal to Civilian Physicians

A circular which has been issued by the undersecretary of state for the medical department of the army, with reference to medicolegal questions in regard to claims for disability, makes the suggestion that the officers of the medical department shall, in case of need, call on civilian physicians for assistance. Appeals may be made to former medical experts of the special reeducation centers, the medical experts attached to the civil courts and physicians holding diplomas of the Medicolegal Institute of Paris. Also specialists may likewise be called on to perform the functions of experts in respect to disabilities.

Extraction of an Intracranial and an Intrapulmonary Projectile

At one of the recent meetings of the Société de chirurgie de Paris, Dr. André Lapointe, hospital surgeon, reported an interesting personal observation. He had occasion to extract from a patient (a young woman suffering from a revolver wound) an intracerebral bullet and an intrapulmonary bullet, near the region of the heart. This was done in one operation, controlled by fluoroscopy. The intracerebral bullet, entering by the left temple, had penetrated to a depth of 7 cm. and was located 3 cm. back of the frontal bone. Under local anesthesia induced by procain and epinephrin, a strip of scalp was excised, the opening was gently enlarged by means of a gouge, and under fluoroscopy, without any special instruments, simply by the use of ordinary blunt forceps, in a few seconds the track of the bullet was located, followed up and the bullet extracted. Irrigation of the encephalic foci by means of warm saline solution was carried out without curetting of the track of the bullet. The original opening was resected and then closed by means of a suture to the center of the strip of scalp, without drainage. The operation had been so simple and the patient had stood it so well that an immediate fluoroscopic examination of the thorax was decided on, this time with the patient in a recumbent position, the first examination having been made with the patient standing upright. In this connection an interesting discovery was made. In the upright position it had been impossible by the rotation of the screen to differentiate the shadow of the projectile from the heart's shadow, whereas in the ventral decubitus position the two shadows were easily dissociated; the projectile was therefore intrapulmonary. The second procedure was immediately decided on and carried out. An incision was made in the sixth intercostal space; the pleura

was opened; but the moment the forceps approached the projectile it disappeared, and a small sanguinolent area was noticeable. After renewed fluoroscopic examination, it was discovered that the bullet had dropped into the pleura, where it was found without difficulty. The postoperative course was excellent and ended in complete recovery.

The point to emphasize in this connection is the great utility of operations controlled by fluoroscopy, for in a case like the present one this is the only means of combining the two procedures in one single operation.

Tetanus and Antitetanic Injections

At one of the recent meetings of the Paris Surgical Society, Dr. Lenormant, hospital surgeon and agrégé professor of the Paris School of Medicine, contributed an interesting communication on the subject of tetanus and antitetanic injections. The war, in this case, as in so many other matters, furnished a wide field for the gaining of experience, and it is important to consider carefully the question of antitetanic serotherapy of which Lenormant is an earnest advocate. First, one must consider the limits of its use both as to time and as to quantity. It is without doubt a matter of paramount necessity to suppress the further elaboration of toxins by the removal of foreign bodies, but it is wrong to assume that such removal brings about the sterilization of the wounds. It is therefore indispensable that the serum be continued in doses sufficiently large (20 c.c.) and that the treatment be kept up as long as the wounds are suppurating. Lenormant saw cases of tetanus at the beginning of the war, in September, 1914, at Montdidier; then again in 1916, while he was chief surgeon of the sector in the Fifth Region and received direct fire from the front the moderately wounded. He observed under these conditions thirty cases of tetanus, almost all of them being late cases which developed from five to eight weeks or more after the wounding. A comparison of these two series of cases is very striking. In 1914 the cases were generalized and were all fatal. In 1916 the tetanus was almost always localized at the outset (painful spasmodic contractures in the wounded member), rarely complicated by trismus, but if so, resulting in quick death. The mortality was only 50 per cent., as compared with 100 per cent. in 1914. The wounded men of the second series had received repeated injections of antitetanic serum. Tetanus immediately became less frequent and less severe in its manifestations and often remained localized. Under these circumstances how can one deny the value of the serum? However, Lenormant reported having seen two soldiers who, in spite of repeated injections of antitetanic serum, presented, one month after being wounded, a typical tetanus with opisthotonos and generalized spasmodic contractures, but even these cases ended with recovery. The serum seems, therefore, to have been incapable of preventing the appearance of the tetanus, although it did lessen its gravity. In delayed operations the practice of injecting antitetanic serum as a preventive seems to be an excellent use, for one must not attach too great importance to anaphylactic accidents, and it is better to give a patient an injection unnecessarily than to have a case of tetanus break out. Pierre Delbet is of the same opinion. He injects 30 c.c. at each injection. The preponderance of localized cases and the benign character of the tetanus as observed in 1916 prove that the serum brought about a relative immunity in the soldiers. As for anaphylactic accidents, Delbet says he has never seen any. He called attention to the fact, moreover, that one should not mistake serum accidents for anaphylactic accidents.

Professor Quenu and Dr. Walther, agrégé professor at the Paris School of Medicine, have never used preventive injections of antitetanic serum in connection with delayed operations on the war wounded, and yet they have never seen any cases of tetanus develop. Walther has been for several years the director of an important service for the reparation of scars, and has performed a considerable number of delayed operations; yet he has had no cases of tetanus. Likewise, Dr. Petit, who has extracted in delayed operations a considerable number of intrathoracic projectiles, has encountered no cases.

Dr. Sicur, a university professor of Val-de-Grâce, continued the discussion, remarking that Roux and Vaillard long since declared that the injection of the serum alone was not sufficient, for by the injection only a certain unknown quantity of the toxins would be neutralized. If the operation has not been complete in every particular, if a focus of infection persists, new toxins develop and tetanus appears. The proper course, therefore, is to make sure, on the one hand, of careful surgical treatment, and, on the other hand, to provide for repeated injections of serum.

Marriages

WILLIAM ROSCOE JEPSON, Assistant Surgeon, Lieut. (j. g.), U. S. Navy, Sioux City, Iowa, to Miss Gladys Lee Wiles of Peconic, Long Island, N. Y., July 9.

BASCOM FRANKLIN MORRIS, Major, M. C., U. S. Army, to Miss Yvonne Randolph Stemmeler, both of New York City, July 14.

MINOR LE ROY HARTMAN, Garden Prairie, Ill., to Miss Minnie Larish of Scranton, Pa., at Elgin, Ill., July 9.

ROY PILLING POTTER, Marshfield, Wis., to Josephine Fritch of Cumberland, Wis., at Minneapolis, July 2.

WILLIAM C. SPANNAGEL to Mrs. Ella C. Nelson, both of East St. Louis, Ill., at Waterloo, Ill., July 1.

BENJAMIN LLOYD KNIGHT, Kenwood Park, Iowa, to Miss Florence McCollister of Iowa City, July 8.

THOMAS STANLEY O'MALLEY, Madison, Wis., to Miss Orpha Kingsbury of Salt Lake City, July 11.

FRANK RAY STEELSMITH, Des Moines, Iowa, to Miss Norma Jones of Matamoras, Iowa, June 29.

THOMAS DYER ALLEN, Chicago, to Miss Florence Waring Sec of Hamilton, Ohio, July 21.

EDWARD CLARK MORSE to Miss Alice Beauregard, both of New Orleans, July 7.

LEE WASHINGTON PRISCOTT to Miss Gladys G. Gates, both of Sloan, Iowa, June 25.

JOSEPH HEINLEY to Miss Irene Rosengard, both of New York City, July 15.

C. LUNSFORD NUCKOLS to Miss Ida Umberger, both of Baltimore, July 4.

Deaths

Charles Porter McNabb, Knoxville, Tenn.; University of Tennessee, Knoxville, 1884; aged 61; a member of the Tennessee State Medical Association; professor of diseases of the digestive system in the Lincoln Memorial Medical College, Knoxville; formerly dean of the faculty and professor of theory and practice of medicine in Tennessee Medical College, Knoxville; died at his home, July 14.

Norman G. Burnham, Denver; Eclectic Medical Institute, Cincinnati, 1851; Homeopathic Hospital College, Cleveland, 1855; aged 89; a member of the Colorado State Medical Society; for forty years a practitioner of Denver; a member of the County Hospital staff, the Denver Board of Health, and one of the founders of the Denver Homeopathic College; died at his home, July 19.

Wellington Wykoff Leonard, Akron, Ohio; College of Physicians and Surgeons, Baltimore, 1883; aged 62; from 1885 to 1889 assistant physician at the Cleveland State Hospital; first president of the People's Hospital, Akron; a director of the Central Savings and Trust Company; died in Mansfield, Ohio, July 13, from nephritis.

Boaz Baxter Cox * Lieut., M. C., U. S. Army, Morgantown, W. Va.; Jefferson Medical College, 1907; aged 39; who entered the United States service, July 13, 1918, was sent overseas in October and was on duty with the American Expeditionary Forces at Dijon and connected with Base Hospital No. 103; died at Dijon, May 9.

Griffin H. Austin, Delacarbon, Colo.; Queen's University, Kingston, Ont., 1893; aged 50; surgeon to the Summley Coal Company, Strong, Colo.; died in a hospital in Pueblo, Colo., July 14, from bullet wounds, said to have been inflicted the day before, by two Mexicans with whom he had gone on a fishing trip, near Waldenburg, Colo.

Harry Pepper * Detroit; Detroit College of Medicine and Surgery, 1906; aged 36; chief of staff of the Jefferson Church and a member of the medical staff of St. Mary's Hospital, Detroit; was stricken with cerebral hemorrhage at Union City, Mich., July 7, and died the same day in a sanitarium at Battle Creek, Mich.

George Frederick Mish, Middletown, Pa.; University of Pennsylvania, Philadelphia, 1853; aged 92; a member of the Medical Society of the State of Pennsylvania; surgeon of the Fifteenth Pennsylvania Volunteer Cavalry during the Civil War; died at his home, July 14, from senile debility.

* Indicates "Fellow" of the American Medical Association

Edward LeRoy McCoy, Indianapolis: Indiana University, Indianapolis, 1908; aged 38; who had been on duty as lieutenant, M. C., U. S. Army, with Base Section No. 3, Services of Supply, American E. F., in London, and was discharged, January 18; died suddenly in Gary, Ind., July 15.

John Brennan Moran * Boston: Harvard University Medical School, 1894; aged 81; first instructor in hygiene in the public schools of Boston; for nine years a member of the Boston school board; a sanitary surgeon in the Civil War; died at his home in Allston, Boston, July 14.

Lindley Ninde Blackledge, Orosi, Calif.: Penn Medical University, Philadelphia, 1880; aged 59; a member of the Medical Society of the State of California; while driving his car over a grade crossing at Orosi, July 16, was struck by a train and instantly killed.

Ellwood B. Warner, Philadelphia: Jefferson Medical College, 1882; aged 59; for nine years school director and for a long time president of the board of council of the Penn Widow's Asylum; died at his home, July 15, from endocarditis and acute enteritis.

Bryan Anderson Barlow, Fort Wayne, Ind.: Johns Hopkins University, Baltimore, 1910; medical director of the Lincoln National Life Insurance Company of Fort Wayne; was killed at Walker, Wis., July 14, by the overturning of his automobile.

William Henry Price, Atlantic City and Point Pleasant, N. J.: University of Pennsylvania, Philadelphia, 1889; aged 54; formerly instructor in diseases of children in his alma mater; died at the Jefferson Hospital, July 8.

Townsend Seely Carpenter, Hinkley, Ill.: Northwestern University Medical School, Chicago, 1892; aged 54; a member of the Illinois State Medical Society; died at his home, July 8, from carcinoma of the stomach.

Samuel Wixom Meade, Farallone, Calif.: Long Island College Hospital, Brooklyn, 1876; aged 70; died at his home, June 29, from an incised wound of the arm, believed to have been self-inflicted with suicidal intent.

Howard Fowler Holmes, Georgetown, Mass.: Harvard University Medical School, 1901; aged 48; a member of the Massachusetts Medical Society; died in Cambridge, Mass., May 22, from tuberculosis.

Ernest Victor Keller * Major, M. C., U. S. Army; St. Louis; Atlanta (Ga.) School of Medicine, 1911; aged 45; on duty at Fort McPherson, Ga.; died in that post, June 3, from cerebrospinal meningitis.

Julius Otto, Chicago: Northwestern University Medical School, Chicago, 1876; Rush Medical College, 1877; aged 61; died at his summer home in McHenry, Ill., July 20, from organic heart disease.

William T. Ferguson, Fort Wayne, Ind.: Royal College of Surgeons of Ireland, Dublin, 1857; aged 84; a pioneer practitioner of Allen County; died at his summer home at Clear Lake, Ind., July 12.

Thomas Franklin Mayo, Newton, Mass.: Tufts College Medical School, Boston, 1909; aged 41; a traveling representative of the United Drug Company; died in a hospital in Macon, July 13.

Clara M. Freeman, San Francisco: California Eclectic Medical College, Los Angeles, 1885; aged 56; died in the San Francisco Hospital, July 12, from carcinoma of the breast.

Emmett Robertson Bradley, Highland Springs, Va.: Medical College of Virginia, Richmond, 1912; aged 39; a member of the Medical Society of Virginia; died at his home, July 10.

Eugene G. Lewis, Stockton, Calif.: Lincoln (Nebr.) Medical College, Feltville, 1907; who has been living on a farm near Modesto, Calif.; died, June 2, from tuberculosis.

Dorman Baldwin, Oneonta, N. Y.; Albany (N. Y.) Medical College, 1877; aged 71; for many years a pharmacist of Jamestown, N. D.; died at his home, June 26.

William Brewster Sawyer, Riverside, Calif.: Harvard University Medical School, 1879; aged 64; local surgeon for the Santa Fe system; died at his home, July 9.

Harry W. Holmes, Cumberland, Ohio: College of Physicians and Surgeons, Baltimore, 1886; aged 62; died at his home, July 10, from cerebral hemorrhage.

John W. Pratt, Gatesville, Pa.: Hahnemann Medical College, Philadelphia, 1873; aged 69; at one time a member of the assembly; died at his home, July 15.

George Barnard Hibbs * Mitchellville, Ia.: University of Illinois, Chicago, 1889; aged 55; died at his home, July 14, from chronic parenchymatous nephritis.

Thomas A. Bounell, Jamestown, Ind. (license, Indiana, 1877); aged 71; a member of the Indiana State Medical Association; died at his home, July 8.

Fred Cannon Peregey, Barnesville, Ohio: Starling Medical College, Columbus, Ohio, 1890; aged 49; died at his home, June 25, from disease of the kidney.

Ellen Adelaide Curtis Richards * Streator, Ill.: College of Medicine and Surgery (Physio-Medical), Chicago, 1897; aged 51; died at her home, July 8.

Wesley A. Trotter, Memphis, Texas: Medical College of Virginia, Richmond, 1852; aged 94; died at the home of his daughter in Memphis, July 6.

George Benton Mitchell, Kansas City, Kan.: Missouri Medical College, St. Louis, 1879; aged 72; died at his home, July 5, from acute gastritis.

Anson Buck, Palermo, Ont.: Jefferson Medical College, 1852; M.R.C.S. (Eng.), 1853; aged 85; died in Toronto, Ont., April 18, from myocarditis.

Rufus Alexander Markham, Waco, Texas: Missouri Medical College, St. Louis, 1885; aged 71; died at his home, July 8, from heart disease.

Edwin S. Muir * Winona, Minn.: University of Minnesota, Minneapolis, 1894; aged 58; twice mayor of Winona; died at his home, July 14.

John Peck Brooks, Providence, R. I.: New York Hygienic-Therapeutic College, New York City, 1860; aged 75; died at his home, about July 14.

Florence Henry Ottmer, Eureka, Calif.: Cooper Medical College, San Francisco, 1887; aged 58; died at his home, June 3, from pneumonia.

Robert Samuel Brown, Sterling City, Calif.: Columbus (Ohio) Medical College, 1883; aged 63; died in Chico, Calif., April 1, from diabetes.

William O. Stone, Bloomington, Ind.: Eclectic Medical Institute, Cincinnati, 1861; aged 85; died at his home, near Bloomington, June 25.

Harris J. Cornish, Walworth, N. Y.; Albany (N. Y.) Medical College, 1870; aged 70; died at his home, April 14, from cerebral hemorrhage.

Silas G. Hertz, Philadelphia: Medico-Chirurgical College of Philadelphia, 1889; aged 87; died at his home, July 8, from cerebral hemorrhage.

Henry W. Latham * Latham, Mo.: Washington University, St. Louis, 1872; aged 67; died at his home, June 25, from cerebral hemorrhage.

Edward Grever, Hazleton, Pa.: University of Pennsylvania, Philadelphia, 1874; aged 81; died at his home, July 7, from cerebral hemorrhage.

Leen Rivers Harrison, Fayette, Miss.: Kentucky School of Medicine, Louisville, 1894; aged 62; died at his home, July 9, from acute gastritis.

Willis Clifford Bills, Durant, Iowa: State University of Iowa, Iowa City, 1885; aged 63; died at his home, July 6, from heart disease.

George L. Dunn, Kansas City, Mo.: College of Physicians and Surgeons, St. Joseph, Mo., 1879; aged 64; died at his home, July 5.

Charles P. Reid, Hampshire, Vt.: Loyola University, Chicago, 1872; aged 70; died at his home, May 13, from valvular heart disease.

Jacob L. Magee, Pine Bluff, Ark. (licensed, Arkansas, 1897); aged 40; died at his home, July 13, from cerebral hemorrhage.

William Gaines, Mount Jefferson, Ohio: Hospital College of Medicine, Louisville, Ky., 1893; aged 65; died at his home, July 7.

Harry Lovell Gillette, Buffalo: Niagara University, Buffalo, 1890; aged 59; died at his home, June 30, from gastric ulcer.

Frank Summers, Dyersburg, Tenn.: Hospital College of Medicine, Louisville, 1877; aged 65; died at his home, July 2.

William Rolfe Whittall * Puyallup, Wash.: University of Illinois, Chicago, 1884; aged 67; died at his home, June 25.

John F. Gibbon, San Francisco: Loyola University, Chicago, 1877; died at his home, July 11.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

"ARSENOVEN S. S." AND "ARSENO-METH-HYD"

Report of the Council on Pharmacy and Chemistry

The Council authorizes publication of the following report. This report declares Arsenoven S. S. of the S. S. Products Company and Solution of Arsenic and Mercury (formerly called Arseno-Meth-Hyd) of the New York Intravenous Laboratory, inadmissible to New and Nonofficial Remedies. The Council takes this opportunity to repeat its warning against the abuses—often dangerous—to which patients are frequently subjected when "intravenous therapy" is employed.

W. A. PUCKNER, Secretary.

Because of inquiries received, the Council took up the consideration of Arsenoven S. S. and Arseno-Meth-Hyd (now sold as Solution of Arsenic and Mercury). The preparations having been referred to a committee for consideration, this committee reported:

ARSENOVEN S. S.

"Arsenoven S. S." is a preparation put out by the S. S. Products Company, Philadelphia. The claims are made that it is "a simplified office treatment for syphilis" and is "a combination of arsenic and mercury for office use, offering maximum efficiency, safety and convenience." According to the company, "Arsenoven S. S." contains Dimethylarsenine 154 grains, Mercury biniodid $\frac{1}{4}$ grain, Sodium iodid $\frac{1}{2}$ grain. With regard to the identity of "dimethylarsenine" the company claims: "This product is a compound of cacodylic acid similar to sodium cacodylate but with a more pronounced therapeutic action." The committee recommends to the Council that "Arsenoven S. S." be declared inadmissible to New and Nonofficial Remedies because of unwarranted therapeutic claims.

ARSENO-METH-HYD

"Arseno-Meth-Hyd" is sold by the New York Intravenous Laboratory, New York City, for the treatment of syphilis. It comes in three dosages, 2 gm., 1.5 gm., and 0.7 gm., respectively. The claim is made that "Arseno-Meth-Hyd 2 gm." contains "2 gm. (31 grains) of Sodium Dimethylarsenate (Cacodylate), U. S. P., and Mercury Iodid 5 mg. ($\frac{1}{12}$ grain)" in 5 c.c. of solution. Physicians are told:

"In primary and early secondary case administer Arseno-Meth-Hyd 2 gm. every sixth day and Mercury Oxycyanide .008 (1/2 grain) intravenously between each injection."

"In Tertiary cases and those of long standing alternate with intravenous injection of Sodium Iodid 2 gm."

The following claims are made for the alleged effectiveness and safety of the cacodylate:

"This methyl compound of arsenic has come into almost universal use for syphilis. On account of lack of toxicity an aggressive routine can be carried on. The simple technique and absence of reactions make it most desirable for the regular practitioner. This large dose gives more uniform results both as healing manifestations and negative Wassermanns."

"Much discussion has surrounded the use of the Methyl Compounds of Arsenic and it has been demonstrated beyond doubt that Cacodylate of Soda proves an effective remedy for syphilis provided that it is properly administered." [sic]

"The low toxicity of this Methyl compound of arsenic is remarkable. It is contraindicated only where a decided idiosyncrasy for even small doses of arsenic exists."

These statements are essentially false and misleading. Cacodylate has not come into universal use in the treatment of syphilis, nor has its usefulness been "demonstrated beyond doubt." On the contrary, H. N. Cole (THE JOURNAL, Dec. 30, 1916, p. 2012) has shown that doses so large as to produce renal injury were almost totally ineffective against syphilis. Obviously, "effective doses" if such exist, are not harmless.

The dosage advised for Arseno-Meth-Hyd may not produce acute toxic symptoms; nevertheless smaller doses have produced nephritic phenomena. The "Arseno-Meth-Hyd" treatment includes the intravenous injection of about $\frac{1}{4}$ grain of a mercury salt. Although this is less than the usual dose (about 1 grain per week), the mercury is probably more effective than the cacodylate.

The committee recommends to the Council that, because of the unwarranted therapeutic claims, "Arseno-Meth-Hyd" be held inadmissible to New and Nonofficial Remedies.

The Council adopted both reports of the committee and declared "Arsenoven S. S." and "Solution of Arsenic and Mercury" ("Arseno-Meth-Hyd") inadmissible to New and Nonofficial Remedies. The committee's reports on these two products impel the Council again to call attention to the undesirable and dangerous abuses to which "Intravenous Therapy" lends itself. There is a distinct field for the intravenous administration of drugs in those cases in which immediate drug action is necessary, or when the medicament is likely to be changed if absorbed through the ordinary channels. Unless such indications exist, however, intravenous administration involves not only inconvenience and expense to the patient, but what is more important, unnecessary danger. The fact that indiscriminate intravenous administration is peculiarly profitable to certain manufacturing houses makes it all the more necessary for the medical profession to be on its guard in this matter.

In this connection it is well worth while to quote the closing paragraph from an editorial on "Intravenous Therapy" that appeared in THE JOURNAL Nov. 11, 1916. It is as true today as when it appeared:

"Intravenous therapy will be most securely advanced if its employment is restricted to such well defined fields. [As those mentioned above.] These fields can be satisfactorily determined only by a scientific pharmacologic study of the action of these drugs when so administered in animals, as well as in man, under conditions in which the results are carefully controlled. The intravenous method is an impressive one, approaching in preparation almost to that which goes with a surgical operation. The patient is usually interested and impressed by this new, and, to him, mysterious method. There is a psychic element in his reaction to the injection which is not a factor in his reaction to the same drug when given by mouth. The intravenous injection of a complex mixture would appear to be particularly reprehensible. Little is known, as has been stated, of the results to be expected from intravenous therapy, even with simple substances. The use of complex mixtures will without doubt react against the proper use of the method."

After the report on Arseno-Meth-Hyd had been presented to the Council, a letter was received from the New York Intravenous Laboratory announcing that the preparation "Arseno-Meth-Hyd" was now called "Solution of Arsenic and Mercury" and expressing a desire to have its products accepted for inclusion in New and Nonofficial Remedies. In view of this letter, the committee's report on "Arseno-Meth-Hyd" and the Council's protest against promiscuous intravenous therapy were sent the New York Intravenous Laboratory for consideration.

The reply of the New York Intravenous Laboratory contained nothing which permitted a revision of the preceding report. The change of the name of "Arseno-Meth-Hyd" to "Solution of Arsenic and Mercury" means little as the name still does not disclose the important fact that the arsenic is present as sodium cacodylate, nor does it tell the character of the mercury compound. The Council voted that "Solution of Arsenic and Mercury" and "Arsenoven S. S." be declared inadmissible to New and Nonofficial Remedies because the therapeutic claims advanced for them are unwarranted (Rule 6) and because the names of these pharmaceutical preparations are not descriptive of their composition (Rule 8).

In filing its reply with the Council, the New York Intravenous Laboratory announced that that document would be circulated to the medical profession. This is of course the firm's privilege. The Council notes, however, with interest, that the reply is devoted almost entirely to points which were not raised by the Council and that it fails to discuss the objections which were actually made.

The reply constantly confuses the efficiency of cacodylate in anemia and in syphilis. The Council's report on "Arseno-Meth-Hyd" does not discuss or even touch on the question of cacodylates in anemia. It is confined to a discussion of the disappointing results obtained with cacodylates as such (i. e., without mercury) in the treatment of syphilis. This attempt on the part of the New York Intravenous Laboratory to confuse the issue and to attribute to the Council an opinion that it has never stated or held is an inexcusable misrepresentation. The company in its reply said:

"We believe that you have previously stated that a solution cacodylate of soda possesses no more action than so much water. In other words, it was inert. Now you try to show that it produces renal injury."

The Council has never declared that cacodylates are inert. In the report it is merely stated "that doses so large as to produce renal injury were almost totally ineffective against syphilis." Neither has the Council stated that cacodylate is "peculiarly dangerous." In fact the absolute toxicity of cacodylates is low but Cole's results were quoted as a caution that "effective" doses are not harmless. A great portion of the remainder of the reply is devoted to disparaging arsenamin—a product that is not involved in this action of the Council, and one about which the physician is amply informed.

As regards the editorial on intravenous therapy, a concession may be made the New York Intravenous Laboratory: intravenous injections are no longer quite as "impressive" as in 1916, but that does not alter the fact that they should be used only when a distinct advantage is to be gained.

"ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY"

Under the caption given above, the *Journal of the Missouri State Medical Association*, in its July issue, speaks editorially as follows:

The Council on Pharmacy and Chemistry of the American Medical Association is a department of our national organization that has not received the plaudits and encomiums of a wildly joyous medical profession nor the grateful praises of the enthusiastic manufacturer of pharmaceuticals. The Council seems indeed to be the unloved child of the entire family of subsidiary bodies of the association. Perhaps the reason for this may be found in the character of its duties, for the Council must expose fraud, sometimes in high places, and protect the physician from being duped by avaricious persons and by persons who are themselves sometimes the victims of their own credulity. It thus happens that the sale of some proprietary article previously held in high esteem by the practitioner proves valueless, perhaps even fraudulent. The practitioner, however, may have credited much of his success in treating certain conditions to that preparation and the maker has had success in accumulating dollars from its sale and both parties emit a loud and vicious roar against the Council, because they both lose money. Nobody wants to be "protected" against making money—make it honestly, if possible, but make it—but this black sheep among the Councils of the American Medical Association insists on their making their money honestly!

Despite many obstacles thrown into its path, the Council on Pharmacy and Chemistry has serenely pursued its allotted tasks, corrected its mistakes, improved its methods, and today stands as the only medium to which the honest physician may turn for information—not misinformation—regarding proprietary articles. During the war the Council and the chemical laboratory were in close cooperation with the Surgeon-General's Office, testing and investigating every article offered to the government for the treatment of the sick soldiers. The variety and the number of fakish and fraudulent stuff offered to the Surgeon-General was a pitiable exhibit of the mental gymnastics of some people. Just now the Council and the laboratory have a new and important field before them, i. e., to protect the physicians against worthless and useless serums, vaccines and synthetics. It will be the Council's unpleasant duty to expose the fraudulent and useless among these articles and stamp truth on those found worthy.

We seem to have wandered from the topic in our caption but not so in reality because the burden of our thought is to

lend our influence to the spread of the motto of the Advertising Clubs of the World, namely, "Truth in Advertising." It is our purpose to stimulate a larger degree of enthusiasm for the work of the Council on Pharmacy and Chemistry and the Chemical Laboratory, a more generous flow of inquiries concerning articles unfamiliar to the physician, and particularly to urge that the words "accepted by the Council on Pharmacy and Chemistry of the American Medical Association" be printed on the label and on all advertising circulars of proprietary articles that have been admitted to New and Nonofficial Remedies. Then, when pamphlets and circulars are received by physicians they will read the statements of manufacturers with sympathetic understanding and with full confidence in the verity of the declarations. The importance of creating just that sort of receptivity in the mind of the prospective buyer is so well known to the astute publicity expert that it is needless for us to dwell on its advantages. Every proprietary article advertised in our journal, in *THE JOURNAL of the American Medical Association*, and in the other state association journals, as well as in several well-edited privately owned journals, does in effect say to the reader that the articles so advertised are accepted by the Council because only proprietary articles so accepted are accepted by us. The fact is further acknowledged when these firms are permitted to exhibit their goods at our annual sessions for again the rule is enforced that only proprietary articles which have been approved by the Council may be placed on display.

Why not complete the circle of ideas—it would not be a "vicious circle"—by printing on labels, in advertisements and circulars, the words: "Accepted by the Council on Pharmacy and Chemistry"?

Correspondence

"USING VARICOSE VEINS FOR INTRA- VENOUS INJECTIONS"

To the Editor:—I agree with Dr. Rosenbeck's statement (*THE JOURNAL*, July 19, 1919, p. 214) that physicians who administer arsenamin occasionally encounter a case in which the veins in the cubital space are difficult to locate. I do not, however, agree with his suggestion to select the varicose veins of the legs. Varicose veins, from a pathologic standpoint, are in a state of subacute or chronic inflammation. This explains the frequent occurrence of acute phlebitis in the lower extremities of females after slight or no trauma. The introduction of an irritant drug, such as arsenamin, into the veins is sufficient to excite an acute exacerbation resulting in thrombosis and complete obliteration. This, perhaps, does not generally follow after the first injection, but will appear in one of the later ones. To improve on this, I have found the dorsal surface of both hands and wrists convenient places to locate veins without any difficulty. A tourniquet is placed over the lower third of the forearm, and within a minute several veins can be seen to stand out prominently.

CHARLES WOLF, M.D., New York.

OPERATION VERSUS ROENTGEN-RAY TREATMENT OF UTERINE MYOMA

To the Editor:—The paper of Dr. Arthur Stein on this subject in *THE JOURNAL*, July 12, p. 95, needs further comment on the other side of the question. Dr. Stein questions the propriety of radiation instead of operation in the first place because of the risk of mistaking a sarcoma of the uterus or ovary for a myoma; and he cites as an instance the case of a young girl in her twenties in which a proposed radiation was abandoned in favor of operation. He then reveals that the resulting operation did not cure the patient. My impression is that the indications in this case pointed to radiation as the most hopeful treatment, particularly at this age. The question of the prevalence of sarcomas among supposed fibromyomas of the uterus has received undue prominence. The differential diagnosis, moreover, is by no means difficult if the patient's history is considered, bearing in mind

that sarcomas present a history measurable in months, while fibromas or myomas may be traced back for years in practically all cases at the time that they reach the gynecologist. One should also suspect the sarcomatous character when a reasonably large growth is discovered in a woman under, say, 28 years of age. But all this is beside the question of the treatment of fibroids, for sarcomas are so rare as to present no practical problem in the matter.

Concerning other possible errors in diagnosis in the absence of an operation, it may be said that radiation is not the worst way to discover these mistaken diagnoses. The possible loss of time cannot seriously impair the result of a subsequent operation. An unnecessary operation, on the other hand, is far more serious.

I question, further, the correctness of the view that the presence of chronic inflammation of the adnexa renders a fibroid not amenable to radiation, for I have frequently employed the screened roentgen ray, and there have been many instances giving the clinical symptoms of inflammatory or catarrhal tubes which yielded ultimately to patient collateral treatment, and in which finally recovery occurred without operation. Barring encysted pus alone in this situation as unsuitable to anything but operation, these cases may be counted on to result in symptomatic cure, with varying degrees of subsequent decrease or disappearance of the harmless residue.

G. BETTON MASSEY, M.D., Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SODA ASH IN WATER

To the Editor:—We have for some time been using soda ash in the feed water of our locomotives, about a half pound to 1,000 gallons. Our employees occasionally drink this water. Is there anything harmful in this practice?

GEORGE K. MEYNER, M.D., Jamaica, N. Y.

ANSWER:—Caustic lime and soda ash are commonly used together for water softening. The amount of soda ash used in the case cited does not seem excessive, but no data are given as to the original hardness of the water. If the water is bacterially pure it is not likely that the health of those drinking the softened water would be endangered. The process of water softening by filtration through artificial zeolite, as suggested by Jackson in the *Journal of the American Water Works Association*, March, 1916, p. 423, is worthy of special attention.

ELIMINATION OF ANTS

To the Editor:—I want to ask you if you can tell me how to kill or eradicate ants that take the entire place, especially the drug room. They are the little red ants. I have tried everything; they still come in. Let me hear if you have anything for them.

J. P. BRANDON, M.D., Essex, Mo.

ANSWER:—A special bulletin prepared by the Department of Agriculture, known as "Farmers Bulletin 740," by Dr. C. L. Marlatt, entitled "House Ants: Kinds and Methods of Control," may be had free on application to the department. This bulletin describes the various ants occurring in North America, giving their habits and life history, and a very particular article on "Means of Controlling House and Lawn Ants." In brief, it is suggested that efforts be made to locate the nest of the ant and that this be destroyed by injecting carbon disulphid, kerosene or gasoline into the opening. Ants, of course, are attracted to houses by food substances, and all food substances should be placed in ant-proof metal containers or in ice boxes. It is not believed that the repellent substances, such as camphor or naphthalene flakes or moth balls, have any value. It is suggested that the ants may be collected by the placing of attractive baits, such as small sponges moistened with sweetened water. These baits may be collected several times a day and the ants swarming on them destroyed by immersion in boiling water. A more

efficient remedy is a syrup poisoned with sodium arsenate. The formula for the preparation of this syrup is: 1 pound of sugar dissolved in a quart of water, to which should be added 125 grains of sodium arsenate. The mixture should be boiled and strained, and on cooling used with the sponges as described. Precautions must be taken in preparing this syrup and safeguarding it afterward to prevent its being the cause of poisoning to human beings or domestic animals.

SUGAR IN FORMULA FOR DIARRHEA IN INFANTS

To the Editor:—In an article entitled "The Etiology and Treatment of the Diarrheal Diseases in Infancy" (*THE JOURNAL*, June 7, 1919, p. 1653), Dr. Lewis Webb Hill, speaking of the treatment of fermentative diarrhea says: "All sugar should be omitted from the milk modification, and the solution boiled for three minutes. One teaspoonful of compound chalk mixture should be added to each bottle." Now, from the first sentence in this quotation, we learn that "all sugar should be omitted from the milk modification"; and in the next sentence, the author advises to add one teaspoonful of compound chalk mixture to each bottle, which means to add a little sugar to each feeding, because compound chalk mixture contains 10 per cent. of sugar. If the author meant that a little sugar given in the shape of compound chalk mixture can do no harm in fermentative diarrhea, his emphatic statement: "All sugar should be omitted from the milk modification," does not imply that. There are many physicians who hold that no sugar at all should be fed to infants with fermentative diarrhea; and not knowing that compound chalk mixture contains sugar would, on the strength of Dr. Hill's advice, prescribe the mixture to their little patients, and thus administer sugar unintentionally. It is in this way that the quotation from Dr. Hill's article is inconsistent and misleading.

LOUIS BECKLE, M.D., New York.

ANSWER:—The question was referred to Dr. Hill, who replies that "the small amount of sugar in chalk mixture does no harm. If any one believes that it may do so, he may use a prescription of chalk and water instead."

GROUP MEDICINE

To the Editor:—Please send me any information or data you may have in connection with group medicine and its practicality for the general practitioner, particularly in rural districts.

E. R. HUNTER, M.D., Washington, D. C.

ANSWER:—The following references may be consulted to obtain a general view of the subject:

EPINEPHRIN TEST FOR HYPERTHYROIDISM

To the Editor:—Please give directions for applying the epinephrin test for hyperthyroidism.

R. R. ELMORE, M.D., Louisville, Ky.

ANSWER:—The test referred to is that called the "skin reaction of Goetsch." Eight minims of a 1:1,000 solution of epinephrin hydrochlorid are diluted with an equal quantity of sterile water and injected hypodermically into the arm. Immediately there is formed an area of blanching around the point of injection, and about the margin of this usually a red areola gradually shading off into the surrounding tissue. In about half an hour the center of the white area becomes bluish gray to lavender, and at the end of from one and a half to two hours, the red areola takes on the bluish or lavender color, while that in the center disappears. This lavender areola remains for about four hours from the time of injection, and is the most characteristic part of the test. Accompanying the local action may be increase in pulse rate with palpitation of the heart and an exaggeration of the tremor and nervous symptoms in general.

A BOGUS MEDICAL DIPLOMA IN AUSTRALIA

The information collected at the headquarters of the American Medical Association regarding medical colleges and the medical profession is now sufficiently complete to prevent the issuing of bogus medical diplomas without an early discovery. Through this information the fraudulent nature of some diplomas issued years ago is being brought to light. For example, the following report gives an account of a diploma which appears to have been issued illegally twelve years ago to an individual now residing at Hobart, Tasmania. Thus the information collected by the American Medical Association is rendering a service to other countries as well as to the United States.

In June, 1917, a letter was received from Mr. Arthur E. Hayward, secretary of the Tasmania Branch of the British Medical Association, Hobart, asking in regard to the legal status of the Harvey Medical College of Chicago, and the character of the medical training given in it. The reply was that the college named became extinct in 1903.

In a second letter, received in September, 1917, Mr. Hayward asked whether any one could have received a degree from the Harvey Medical College in 1907, and requested some legal declaration to prove that no degrees had been issued by that college after 1905. In reply, a certified copy of a resolution which appeared as an insert in the annual announcement of the Jenner Medical College, Chicago, issued in 1905, was sent showing, that after the organization of a "Harvey-Jenner Medical University," the Harvey Medical College affiliated itself with, and requested its remaining students to enroll for the session of 1905-1906 in the Jenner Medical College. Sept. 7, 1917, we wrote to the secretary of state of Illinois, asking what final disposition had been made of the charter of the Harvey Medical College. The reply stated that the charter was canceled, July 1, 1902, for default in filing an annual report. A copy of the reply was forwarded to Mr. Hayward.¹

Nothing more was heard until in October, 1918, when two cablegrams were received signed "Scott, President, Medical Council," asking whether a student named Ratten had, at any time, attended or graduated from Harvey Medical College. The cablegram stated that Ratten held a diploma from the college named, dated March 8, 1907. The president was informed that Ratten was not recorded either as a student or a graduate of the Harvey Medical College.

In December two more cablegrams were received from Dr. Scott asking whether any Harvey Medical College was existing in Chicago in March, 1907. The reply was in the negative.²

The reason for the inquiries was made more clear in January, 1919, when a letter from Dr. Robert F. Scott, president of the Medical Council of Tasmania, explained that the cablegrams referred to one Victor Richard Ratten. He said that the council of which he was president and which was a statutory body, constituted for the purpose of keeping a register of the qualified practitioners of Tasmania, was on

the point of being abolished because it had dared to run counter to the premier, and had questioned Ratten's qualification.

A copy of the Hobart *Mercury* of Dec. 12, 1918, enclosed with Dr. Scott's letter, contained a report of a "Ratten Royal Commission" which, it was shown, had been appointed by the premier of Tasmania to inquire into charges against Ratten made by the Tasmania Branch of the British Medical Association. In the commissioner's report a diploma said to have been held by Ratten was reproduced as follows:

HARVEY MEDICAL COLLEGE

CHICAGO Coat of Arms. ILLINOIS.

To all to whom this Diploma shall come, Greeting:

Be it known that VICTOR RICHARD RATTEN, having completed the Course of Study required by this institution and having passed a satisfactory examination and recommendation by the Faculty as qualified to enter upon the practice of Medicine and Surgery; and by virtue of the powers vested in us by the State of Illinois, we hereby confer upon him the Degree of

DOCTOR OF MEDICINE

with all the rights, privileges, immunities, and honours pertaining thereto.

IN TESTIMONY WHEREOF, the Harvey Medical College has caused this Diploma to be signed by the President and Secretary of the Board of Directors, and the official Corporate Seal to be hereto affixed at the City of Chicago in The State of Illinois, U. S. A., this eighth day of March, A. D., 1907.

HARRY P. HESLEY, M.D., Dean of Faculty,
M. A. BROWN, M.D., Secretary of Faculty,
W. E. WARRER, M.D., Secretary of Board of Directors,
WILLIAM GALE FRENCH, A.M., M.D., President of Board of Directors.

INQUIRY BY COMMISSIONER

In his report, the commissioner said he had seen the cable replies from the Council on Medical Education in regard to the nonexistence of the Harvey Medical College but, as a result of other inquiries, concluded, nevertheless, that it still existed. The commissioner stated that he had sent the following cablegram to two individuals whose names were attached to Ratten's diploma—a paper, the validity of which had been questioned:

Have before me diploma of Victor Richard Ratten issued by you and others on behalf Harvey Medical College, dated March, 1907. Did you issue same, and what are relations of Harvey Medical College and Harvey-Jenner College?

To this the commissioner states he received the following replies:

Am looking up records; will cable to-morrow.—W. G. French.

And on the next day:

Diploma issued Victor Richard Ratten, March, 1907, by me and others on behalf Harvey no connection with Harvey-Jenner College.—W. G. French.

Cabled information received by the commissioner through the Continental and Commercial Bank of Chicago showed that Harvey Medical College, Chicago, was in 1907 a duly chartered institution.³ Then follows the account of an examination of "Dr." Ratten. In answer to questions asked by the commissioner, Ratten is reported to have stated under oath that he was surgeon-superintendent of Hobart General Hospital; that he recognized the certificate (evidently the diploma of the Harvey Medical College already reproduced), and that it had been issued to him by the Harvey Medical College which, he said, was then an existing institution. No questions are recorded in the report, asking whether the college ever held classes or carried on medical teaching or whether Ratten was ever in attendance, or studied medicine at the Harvey Medical College. In his report the commissioner concluded that the Harvey Medical College existed in 1907 and that the diploma which Victor Richard Ratten produced in 1907 was granted to him by the college named.

COMMENTS REGARDING THE INVESTIGATION

Notwithstanding the fact that evidence was presented which questioned the validity of Ratten's diploma, the commissioner, according to the reports, secured evidence from those whose names were attached to the diploma and *who could not be expected to state that the diploma was invalid!*

³ The cable did not ask whether the college existed on March 8, 1907, the date on Ratten's diploma.

¹ The fact that one Harvey Medical College had been chartered in 1905, and that its charter was not mentioned in the report of the secretary of state of Illinois, and was not revealed in the report of the commissioner, is a fact.

² As stated later in this report, the charter of the Harvey Medical College had been received in 1907; the statement is true, nevertheless, that no institution of that name has had a bona fide existence, as a duly chartered, faculty, published announcements, or which had opened a list of students or conducted medical teaching.

The character of the investigation is further referred to in an editorial appearing in the *Medical Journal of Australia* of Dec. 28, 1918, page 523, as follows:

Notwithstanding the fact that a well-known official of the American Medical Association, the most reputable and representative medical institution in the United States of America, maintains that the Harvey Medical College did not exist in 1907, and that Ratten was neither a student nor a graduate of that body, the Royal Commissioner has found that a Harvey College did not exist in 1907, but actually issued a diploma to Victor Richard Ratten, setting out that he had passed through the prescribed course of study, and had satisfied the "Faculty" that he was qualified to practice medicine. It will be noted from the proceedings of the Commission that the Royal Commissioner failed to wait for information from the Attorney-General of Illinois, and merely announced his intention of obtaining the assistance of the American Government. Instead of seeking and acquiring official information from the most reliable source, the Royal Commissioner adopted the extraordinary procedure of communicating with the persons whose names appear on the diploma produced by Ratten. It is significant that those names are, so far as we are aware, unknown in Australia, and that, despite the repeated statement of the Secretary of the American Medical Association that the Harvey Medical College did not exist in 1907, the cabled assertion of the persons named on the document appears to have been accepted as final.

MORE RECENT INFORMATION

The information received from Dr. Scott and from the commissioner's report led to a further investigation in regard to the Harvey Medical College by the Council on Medical Education. Following a conference with Mr. Francis W. Shepardson, director of the department of registration and education, the latter examined the records in the office of the secretary of state and discovered that, instead of one, three institutions had been incorporated which bore, or included, the name of the "Harvey Medical College." Mr. Shepardson reported these as follows:

1. Harvey Medical College, incorporated, Nov. 23, 1891, by Alva Camp, Willard P. Case and Charles D. Camp. The subscribers to the capital stock were W. P. Case, 2 shares; G. E. Giles, 1 share; J. C. Ivey (or Irey), 10 shares; Charles D. Camp, 237 shares. Ivey and the two Camps and Frank C. Vierling, Frank Baker and J. R. Holmes made up the first board of trustees. This charter was canceled, July 1, 1902, because of failure to file an annual report.⁴

2. Harvey Medical College, incorporated, Aug. 28, 1894, by James A. Strong, George Warren Reynolds, and Charles D. Camp. These were the subscribers to the capital stock and the members of the first board of trustees. This college made annual reports until 1903. The charter was canceled by the secretary of state, March 5, 1904. It was reinstated, March 19, 1907. It has made annual reports each year up to and including Feb. 11, 1918. In that report it is said that the corporation is not now in actual existence, but "said corporation expects to resume active business as a medical college and desires to keep its charter intact." President, Dr. Frances Dickinson, 2750 W. 35th St., Chicago, care of Albert Dickinson Seed Company. Secretary and treasurer, Phillip S. Brown, Montana Bldg., Missoula, Mont. Their term of office "until their successors are elected." The statement also says that "the corporate seal is mislaid."

3. This is evidently the institution referred to by Secretary of State Emerson in his letter of Sept. 10, 1917, to which reference has already been made in this report.

3. Harvey Medical College and Hospital, incorporated, Jan. 9, 1907, by William G. French, Harry P. Hurley, W. E. Warner and L. W. Rowell. Nov. 2, 1908, the name of this institution was changed to Jackson University, W. M. Marquardt being secretary, and W. G. French as president. Sept. 27, 1909, the name was changed to Jefferson University, W. M. Marquardt being secretary, E. S. Stafford, vice president, and W. G. French signing his name as notary public. This charter was canceled, on May 17, 1912, a proper notice of dissolution being filed by French and others.

Statements in the catalogues of the only bona fide Harvey Medical College—the only one which had the essential teachers and laboratories; the only one which openly enrolled students and issued annual announcements—show that the first two charters were secured for that school. Its last announcement that of 1904-1905, contains a historical statement which says that the Harvey Medical College was first incorporated in 1891 and for certain reasons obtained a new charter in July, 1894.

The information on file in our biographical department

shows that the Harvey Medical College ceased to hold classes and teach students at the close of the session of 1904-1905; that in the session of 1905-1906 the students remaining were urged to enroll and finish their training in the Jenner Medical College; that its charter had expired in 1904, and that, although the charter was reinstated, March 19, 1907, the college did not resume medical teaching.

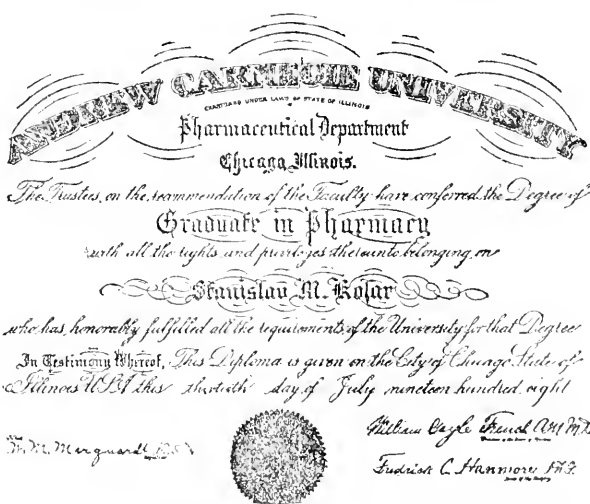

WAS RATTEN'S DIPLOMA VALID?

From August, 1894, to July 1, 1902, the bona fide Harvey Medical College had two charters. The first of these was canceled, July 1, 1902, and the second was canceled in 1904. The latter was not revived until March 19, 1907—eleven days after the date on the diploma issued to Victor Richard Ratten.

According to Mr. Shepardson's statement, in their reports, the officers of this college stated that the corporation was not in actual existence, but expected at some future time to resume active business as a medical college and for that reason desired to keep the charter intact. This shows that the institution was making no attempt to conduct classes or to teach medical students and, therefore, was not issuing degrees. As will be noted, neither of these charters were alive, March 8, 1907, the date on the diploma issued to Victor Richard Ratten.

Charter 3, that of the French-Hurley-Warner-Harvey Medical College and Hospital, incorporated, Jan. 9, 1907, is the only one which was legally alive, March 8, 1907. The names of the incorporators appear to be identical with those signed to Ratten's diploma. Although the name Harry P. Hurley appears on the printed reproduction of Ratten's diploma, this could easily be due to mistaking the written "r" in Hurley for an "s." Note, however, that the name of the institution on the diploma issued to Victor Richard Ratten is not the "Harvey Medical College and Hospital" but

Doctor's "Diploma" Sells for \$75; Its Grantor Is Quickly Arrested

The above is a reproduction of a diploma of the Andrew Carnegie University as it was reproduced in the *Chicago Tribune* of Aug. 2, 1908, accompanying the printed news item, which is also reproduced herewith. The two lines above the diploma were added in the *Tribune's* article. Note the signatures on the diploma.

4. This is evidently the institution referred to by Secretary of State Emerson in his letter of Sept. 10, 1917, to which reference has already been made in this report.

the "Harvey Medical College"—an institution which was not alive, March 8, 1907. This confusion of names throws still more doubt on the validity of Ratten's diploma.

Even after securing a charter for an institution, which seems to have had no existence except on paper, the French-Hurley-Warner crowd appears to have issued a diploma to Victor Richard Ratten under the name, not of the institution they had chartered, but under the name of what was a bona fide institution between 1891 and 1905. Additional light is thrown on the practice of those who incorporated the Harvey Medical College and Hospital by the fact that after a year and ten months the name of that institution was changed to the "Jackson University."

and ten months later was again changed to the "Jefferson University." Note also in Mr. Shepardson's account of the Harvey Medical College and Hospital that after the name was changed to the Jackson and Jefferson Universities, one W. M. Marquardt was named as secretary and W. G. French as president. This indicates a relationship between the French-Hurley-Warner crowd with another institution reported to have existed on paper only, the Andrew Carnegie University, which in 1908 issued an alleged illegal diploma bearing the names of W. M. Marquardt and William Gayle French.

Another statement bearing on the validity of Ratten's diploma is that of Dr. Frances Dickinson, who was president of the bona fide Harvey Medical College during its existence, who says that any diploma of Harvey Medical College issued after 1894 was invalid unless it bore her personal signature. She also says that neither French, Hurley nor Warner ever had any relationship with the Harvey Medical College either as officers or as faculty members.

RECORD OF WILLIAM GAYLE FRENCH

The commissioner's report gives "William Gale French, A.M., M.D., President of Board of Directors." The records of the American Medical Association show that William Gayle French was born in 1885; graduated from Hahnemann Medical College and Hospital, Chicago, in 1906; was licensed in Texas and in Michigan in 1907, in Indiana in 1908 and in Illinois in 1913. The medical directories show frequent changes of address as follows: In 1906 in Brook, Ind.; in 1909, Greensburg, Ind.; in 1910, Indianapolis; in 1912, Kingsbury and Laporte, Ind., and 1914 and 1916, inclusive, Chicago. It is William Gayle French also who is reported among the incorporators of Harvey Medical College and Hospital.

The cablegrams received by the commissioner at Hobart leads one to believe that this is the French whose name appears on the diploma issued to Victor Richard Ratten. It is not probable that there are two individuals having names so nearly alike.

In the Chicago Tribune of Aug. 2, 1908, was published a photographic reproduction of another alleged bogus diploma—one from the "Andrew Carnegie University" which bears the name of William Gayle French as "President of the Board of Trustees," and of W. M. Marquardt as "Registrar." According to the report in the same paper, French was arrested by two detectives in the act of delivering the diploma and receiving \$75 for it. The report also says that the Andrew Carnegie University has no existence except on paper. This report indicates, therefore, that William Gayle French was not averse to handling bogus diplomas.

News clippings from the Chicago Herald for Oct. 5, 1915, and the Chicago Tribune for Oct. 20, 1915, report the arrest of William Gayle French and another physician in connection with an alleged abortion produced on a young woman who died under the operation. The man with French seems to have been held to the grand jury; French, himself, was exonerated. French then changed his address to Detroit, Mich.

A clipping from the Detroit Times, June 26, 1918, under the head "Warrants Out For Quacks," states that warrants were issued for the arrest of Dr. W. G. French charging him with violating the state law against advertisements for the cure of venereal diseases. In the Detroit Times of July 1, 1918, under the heading "Quacks on the Jump to Escape," the following statement appears:

Drug Clerk Tells the Police.

Kolar told the visitors that he would think the matter over, and after a while he would call again and he would be able to give them a definite answer.

He reported the proposition to Detectives Houkhan and Brophy of the Lawanda station. They told him to pretend that he wanted to purchase the diploma and in that way the men would be trapped.

After several interviews with Kolar, the detectives were informed that the diploma was ready and would be given him for \$75. It was arranged that he was to meet French and Jindra yesterday afternoon at the Great Northern hotel.

Delivery of the "Diploma."

The detectives noted that Morney Hoffman, and he was at the Great Northern when Kolar appeared at 4 o'clock. French and Jindra shook hands with Kolar and left him from the hotel to Wabash avenue and Washington street. Hoffman and the two detectives trailed along behind.

When Kolar and the two "doctors" reached Wabash avenue and Washington street French disappeared for a few minutes. When he returned he carried in his arms the bogus diploma.

Kolar was taken by the men to the entrance of a building where he was shown the diploma with its name nicely written on it. "Andrew Carnegie university" was the name of the college, and the diploma was signed by French as "president of the Board of Trustees." The names "Frederick C. Hahnemann" is signed to the diploma as dean of the faculty, and the registrar is "W. M. Marquardt."

Attorney Hoffman says that the latter named person is the wife of French.

Detectives Pounce on the Pair.

After Kolar had handed over the \$75 to the men and was walking away with the diploma the detectives rushed upon and arrested French and Jindra. They were charged with operating a confidence game.

Jindra lives at Twenty-fifth street and Trumbull avenue. He at one time was connected with a hospital in Europe. French lives at Hoffman avenue. He claims to be a graduate of the Hahnemann Medical college and has practiced in Texas.

Calls Them a Bold Pair.

"They are the boldest pair that I have ever met with," said Attorney Hoffman. "I have seen that they purchased a lot of surgical instruments and medical supplies, and they were going to Milwaukee to open a hospital. The Andrew Carnegie institution, which they claimed to be at the head of, does not exist. I would not be surprised to learn that they have sold a number of the diplomas."

The quacks are on the run. Dr. W. H. French whose "sick men" advertisements appeared in the detection of readers of many newspapers, has left the city two jumps ahead of the warrant which Special Prosecutor Henry A. Montgomery swore out against him.

The Chicago and Detroit papers made other statements similar to those quoted reflecting on French's character. A letter dated July 23, 1918, from B. D. Harrison, secretary of the Michigan State Board of Registration in Medicine, says:

Dr. William Gayle French, Detroit, "Two warrants issued against him, one for immoral advertising and the other for obtaining money under false pretenses. Warrants were not served owing to the fact that he left for parts unknown before service could be effected."

5 See the reference to these men in the description of the French-Hurley-Warner Harvey Medical College and Hospital.

CONCLUSION

As we have seen, two institutions were chartered bearing the name of "Harvey Medical College," and one was chartered with the title "Harvey Medical College and Hospital." The last named was the only institution having a legal existence, March 8, 1907, the date on the diploma issued to Victor Richard Ratten; but even this was not chartered until Jan. 9, 1907, only two months prior to the date on Ratten's diploma, and the signatures on Ratten's diploma would also indicate that this is the institution which issued it. It was not in existence long enough, however, to have given even a single term of instruction, and there is no evidence to show that it ever had a college building large enough for the conducting of classes, that it ever possessed a faculty or laboratory equipment, or that it ever issued an announcement or did actual teaching. Note, also, that the legal title of this institution is the "Harvey Medical College and Hospital," whereas, the heading of the diploma issued to Ratten, as reproduced in the royal commissioner's report, was the "Harvey Medical College." Again it is evident that the names signed to the diploma issued to Ratten are of persons who had no connection, official or legal, with the institution which issued it. Again, the institution named on the diploma issued to Ratten had no actual existence later than 1905, so far as an organized faculty, laboratory equipment and teaching facilities are concerned, and its charter, which had been canceled in 1904, was not revived until March 19, 1907, eleven days after the date on Ratten's diploma. All these facts indicate the fraudulent character of the diploma issued to Victor Richard Ratten, which evidence is strengthened by the fact that a year later one of the persons named as having signed Ratten's diploma is reported to have been caught in the act of selling an alleged bogus diploma to another individual.

This matter is still under investigation by the Tasmania Branch of the British Medical Association.

Social Medicine, Medical Economics and Miscellany

THE HEALTH OF MUNITION WORKERS

The final report of the British Committee on Health of Munition Workers, reprinted in this country by the Bureau of Labor Statistics in Bulletin 249, contains a large amount of data accumulated by the committee during the four years of its existence. Different sections of the 375-page pamphlet are devoted to almost every phase of industrial welfare. In the concluding section of the report, the committee has summarized its findings in ninety-two paragraphs which constitute a concise summary of the industrial experiences of the five years of war.

The committee finds that there has been an increased appreciation of the whole subject of industrial hygiene; that the environment and conditions of employment of the worker are vastly better than they were, although there is still much need for further improvement. This development is attributed to three causes: the adoption of the recommendations contained in previous reports of the committee; the establishment of a health and welfare section under the Ministry of Munitions, and the increased powers for securing the welfare of workers conferred on the home office. Regarding the relation of fatigue and ill health to industrial efficiency, the report says, "Without health there is no energy; without energy there is no output. More important than output is the vigor, strength and vitality of the nation. The conditions essential to the maintenance of health are, first, personal conditions favorable to the body itself (e. g., food, fresh air, exercise, warmth and adequate rest, and, secondly, a satisfactory environment, including sanitary factories, suitable hours of work, good housing accommodation and convenient means of transit."

Regarding the industrial employment of women, which has greatly increased during the war, the committee finds that

up to the present there has been no marked breakdown in the health of women in industry. As to hours of labor, the scientific data collected and the experience gained during the past two years show that the length of hours recommended in January, 1916, namely, thirteen to fourteen hours a day, are too long and can be reduced without loss of output; that by economizing time the hourly output can be increased, and that the time is now ripe for further substantial reduction in working hours. Sunday labor is unpopular, uneconomical, and not productive of increased output. Night work is uneconomical owing to higher wages, inferior heating and lighting and more difficult supervision. Lost time is due to many causes, as sickness, accidents, bad housing, poor transportation and bad weather. The proportion of lost time due to sickness is greatly underestimated. Any sound system for dealing with industrial disease must be aimed at prevention, and the treatment must deal with the beginnings of the disease. The committee finds that a large number of industrial accidents are preventable and that it is to the interest of all parties that they should be reduced to a minimum. Cleanliness in factories is essential, not only for health, but also on account of its bearing on the self-respect of the worker. Regarding welfare work in industry, the committee feels that the time has not yet come when a definite judgment can be passed, nor is it possible to prophesy its future lines of development. The confidence and support of the workers has yet to be obtained. The report contains a large amount of detail material, charts, photographs, tables, etc., on all the problems that have arisen in the munition factories during the time of the war.

THE CONTROL OF INFECTIOUS DISEASES IN THE DURAND HOSPITAL

What may be accomplished by a careful control of infectious diseases is brought out in the recent report, by Dr. George H. Weaver, on the work of the Durand Hospital of the John McCormick Institute for Infectious Diseases, Chicago, covering the first five years of its existence. The hospital is conducted for poor patients. During the five years, 2,817 patients were admitted, the service being largely devoted to diphtheria, measles, scarlet fever, poliomyelitis and epidemic meningitis. However, a large number of other infections are listed in the table of diagnoses.

One of the great dangers of hospital care of infectious disease is cross- or double-infections. During the five years, there were twenty-three cases of such infections in the hospital, or 0.8 per cent. of the admissions. Eight of these cases were traced to exposure in isolation rooms on entrance, and could have been avoided if each patient had been individually isolated. The record, however, is excellent, since another large infectious disease hospital, also conducted on aseptic technique, shows an existence of cross infection varying from 1.1 to 4.6 per cent. In an effort to prevent secondary infections entirely, each patient is isolated in a separate room until the incubation period for extramural infection has passed. Such procedure is necessarily expensive, but the cost is offset by the shorter time of hospital care and by the elimination of severe—and sometimes fatal—results that follow double infections.

During the five years, 892 patients with diphtheria were treated. There was a mortality of ninety-three cases, or 11.6 per cent. Excluding patients who died within twenty-four hours after entrance, the rate is 5.6 per cent. This difference is an indication of the importance of early administration of diphtheria antitoxin. Seventy-two patients, or 9 per cent., developed secondary paralysis. The average amount of antitoxin given in a single case was 22,000 units. This was usually injected intramuscularly, but in a few serious cases directly into a vein. Severe shock sometimes observed after intravenous injections has led the hospital to abandon this method except for very urgent cases.

The experience of the hospital with diphtheria carriers has been described in various publications. After a study of numerous methods, it has been found (as reported by Friedberg) that the removal of the tonsils is practically always followed by prompt disappearance of the bacilli.

Apparently the conditions in the diseased tonsils prevent not only the action of antiseptics and other substances but also the ready entrance of antibodies from the blood.

Of 164 patients with measles, eleven died, or 6.7 per cent. In the differential diagnosis from German measles and scarlet fever, it has been found that the examination of throat smear is of value because the bacterial pictures are quite characteristic in each disease.

Of 1,305 patients with scarlet fever treated in the hospital, fifty-six died, a death rate of 4.3 per cent. This figure is slightly below that recorded for 850 cases in the Alexandria Hospital of Montreal with a mortality of 8 per cent., or 1,529 cases in the Providence City Hospital, with a rate of 5.1 per cent. Nephritis was present in 150 cases, or 11.4 per cent., including only cases which exhibited microscopic evidence of nephritis. Polyarthritides, nonsuppurative in character, occurred in 158 patients, or 12.1 per cent. Otitis media was found 220 times, or in 16.8 per cent.; mastoiditis fifteen times, or 1.1 per cent. The experience in the cases of mastoiditis has further impressed the conclusion that it is dangerous to wait for spontaneous cure, and that an early operation offers the only opportunity for avoiding extensive local destruction of tissues and general septic infection. Appendicitis developed as a secondary complication in four cases.

In a study of the development of infections among nurses and attendants, it was found that certain infections must be attributed to mouth spray. For this reason, gauze masks were first employed in the hospital and have been continuously employed since June 1, 1916. It is encouraging to note that good results have been achieved in the protection of nurses and attendants by this method.

Medicolegal

Pregnancy and Good Health

(National Council of the Knights and Ladies of Security v. Glenn (Fla.), 80 So. R. 516)

The Supreme Court of Florida, in affirming a judgment in favor of plaintiff Glenn, on a beneficiary certificate issued by the defendant to his wife, holds that pregnancy is not a personal ailment or condition of bad or unsound health, so as to violate an agreement or stipulation that a member of a beneficiary society shall not be reinstated after suspension for nonpayment of dues, unless such member is in good health at the time of the reinstatement. The court holds further that a plea that the insured was "not in good health" at the time of her reinstatement was too vague and indefinite, and that the defendant might be required to set forth definitely and specifically in what respect the insured was not in good health, and the nature of her ill health.

Physician Not Liable for Testifying as to Insanity

(O'Connor v. Loret (Iowa), 170 N. W. R. 776)

The Supreme Court of Iowa, in affirming a judgment that was rendered on a directed verdict in favor of the defendant, a physician, who was sued for damages for alleged libel, says that a brother of the plaintiff caused an information, addressed to the commissioners of insanity, to be filed in the office of the clerk of the district court, alleging that the plaintiff was insane and a fit subject for custody and treatment in the state hospital. A warrant was issued and delivered to the sheriff of the county commanding him to take her into custody, and bring her before the commissioners. The return of the sheriff was not dated but certified that he took the plaintiff into custody. She was not, however, taken before the commissioners. The defendant, who had been previously employed as her physician, was subpoenaed, sworn, and examined on the trial before the commissioners. His testimony was reduced to writing and signed by him. He testified that, in his judgment, the plaintiff was insane and should be sent to the hospital for proper care and treatment.

All the foregoing proceedings were had on the day the information was filed. On the following day the plaintiff was taken by the sheriff to the hospital at Mount Pleasant, where she was confined for a period of about five months, when she was paroled to her mother, and later she was discharged as cured.

The plaintiff in her petition in this case demanded damages in a large sum, alleging that the statements uttered and signed by the defendant before the commissioners were false, malicious and libelous. The principal defense relied on by counsel for the defendant was that the statements complained of were made by the defendant as a witness under oath on the trial, and therefore privileged. The plaintiff sought to avoid the plea of privilege on the ground that no notice was served on her of the proceedings before the commissioners, and that they were wholly void. But the Iowa statute does not require notice of the filing of an information alleging insanity, or of trial thereon, to be served on the person whose sanity is to be investigated. Section 2265 of the code provides that the accused shall be taken before the commissioners, unless they shall be of the opinion that to do so would probably be injurious, or attended with no advantage to the person alleged to be insane, in which case the hearing may be conducted without his presence. Any citizen of the county or relative of the person alleged to be insane may appear and resist the application in person or by counsel. Provision is also made for an appeal, as well as that all persons confined as insane shall be entitled to the benefit of a writ of habeas corpus, and that the question of insanity shall be decided at the hearing thereon. The record did not disclose an affirmative finding by the board that the condition of the plaintiff was such that it would be injurious for her to be present at the trial, or that this would not be of advantage to her, but presumptively such was the judgment and finding of the commissioners.

There was nothing in the record to indicate that the defendant was actuated by improper motives, or that he acted in bad faith toward the plaintiff. He was subpoenaed, sworn, and examined as a witness, and his testimony was corroborated by that of other witnesses. Whether an action for libel could be maintained against him, if the proceedings had been for some reason invalid, the court need not determine, as that question was not before the court. The proceedings before the commissioners were, so far as the record disclosed, in all respects regular and valid, and all of the statements made by the defendant were clearly privileged.

Husband Communicating Venereal Disease to Wife

(Holmes v. Holmes (Iowa), 170 N. W. R. 793)

The Supreme Court of Iowa, in affirming a decree granting the plaintiff a divorce for alleged cruel and inhuman treatment by the defendant in communicating gonorrhea to the plaintiff, his wife, says that the authorities are uniform that an act such as was complained of here, if proved, constitutes cruel and inhuman treatment, under the statute, such as justifies the granting of a divorce. The holding is that the communication by a husband of a venereal disease to his wife, knowingly, is good and sufficient cause for a divorce, and is cruelty of the most flagrant kind. However, the mere fact that the wife is found infected with this disease after marriage is not in itself sufficient to justify the court in granting a divorce. In *Holthoefer v. Holthoefer*, reported in 47 Mich. 260, 643, 11 N. W. 150, it is said, in substance, that the evidence from the physician and nurses attending disclosed that the complainant was afflicted with a venereal disease. No charge was made and no suspicion suggested against the chastity of the complainant. On the other hand, there was no evidence against the defendant except the single fact that his wife was found to be diseased. If it were impossible that a virtuous wife should contract such a disease otherwise than from the husband, perhaps the facts already stated should, under the circumstances, be sufficient proof of his guilt. But it was conceded that the wife may innocently acquire the disease in other ways, and the wife's case must be supported by negative testimony that she was not in any manner exposed.

AMERICAN ASSOCIATION OF ANESTHETISTS

Seventh Annual meeting, held at Atlantic City, N. J., June 9-10, 1919

The President, DR. WILLIAM B. HOWELL, in the Chair

The Acid Base Regulatory Mechanism During Anesthesia

DR. S. P. REIMANN, Philadelphia: In anesthesia there results a compensated acidosis in from 30 to 85 per cent. and an uncompensated acidosis in from 15 to 20 per cent. of routine operative cases. The reduction in the bicarbonate, which has been found to occur after anesthesia and operation, in our studies, averaged from 5 to 15 c.c. of carbon dioxide per hundred cubic centimeters of plasma. This decrease, in the majority of cases, does not approach the limit of compensated acidosis. It now seems thoroughly established that the sum total of ketone bodies in both the urine and the blood after anesthesia and operation practically determine the amount of alkali which has been withdrawn from the available quantity in the body. The protection of the patient from acidosis rests in limiting sub-oxidation and in supplying the body with alkali. Further studies have confirmed that the ammonia and titrable acidity of the urine are increased after anesthesia. These acids are neutralized, as they are formed by sodium bicarbonate and ammonia and also by other available but less easily mobilized bases, such as calcium and magnesium. The salts of the acids are then excreted and thus eliminated from the body. The symptoms which acidosis will produce vary in intensity from headache, nausea, and vomiting, gas pains and mental dulness, to coma and death. Clinically, acidosis plays an important part in unfavorable postoperative symptomatology. The following factors were found to influence uncompensated acidosis: extreme age, impaired kidney function, exhausting diseases, prolonged sepsis, duration and depth of anesthesia, hemorrhage and preoperative fasting. The condition of shock is always associated with uncompensated acidosis. It is important, clinically, to realize that patients who show a low alkali reserve before operation will always show a greater diminution after operation. In handling acidosis a patient, before operation, showing a bicarbonate content of 58 c.c. or less should be given the benefit of alkalization by means of sodium bicarbonate, although further studies may show the use of magnesium and calcium to be equally important. It must be remembered that too much alkali may do as much harm as excess acidity. Consequently a second analysis two hours after alkalization should be made to indicate whether the desired result has been effected.

Toxic Effect of General Anesthetics in Naturally Nephropathic Animals

DR. WILLIAM DE B. MACNIDER, Chapel Hill, N. C.: My experiments warrant the following conclusions: (1) The use of an anesthetic is associated with a reduction in the alkali reserve of the blood, which is very marked in naturally nephropathic animals; and (2) a decrease in kidney function; and (3) that if the alkali reserve of the blood during an anesthetic can be kept above 7.9, the animals not only remain diuretic, but also responsive to various diuretic solutions. Histologically the animals with marked reduction of alkali reserve, anuria and nonresponse to diuretics show a severe swelling and necrosis of the tubular epithelium, especially that of the convoluted tubules, and the occurrence of large

amounts of fat in the tubular epithelium, especially that of the ascending limb of Henle's loop.

A Simple Method of Administering Ether with Oxygen, and Its Advantages

DR. JOSEPH E. LUMBARD, New York: In this method the oxygen from a low pressure tank is sent through the ether container to a special facemask, covered with gauze and a rubber dam, with an air vent left on which induction by the drop method of ether or ethyl chlorid may be carried out. The oxygen may be sent through the vapor devices of Gwathmey, Lumbard and others to secure dosimetric control, but the simpler method suffices for all routine operations, even in the largest hospitals. Of all methods it gives the operator the utmost relaxation and deepest surgical anesthesia consistent with the safety of the patient, and a rapid and uncomplicated postanesthetic recovery. With proper accessories, the technic may be used for oral, nasal or endopharyngeal anesthesia, in which methods the use of oxygen is especially advantageous when the operative puncture is apt to embarrass respiration.

Influence of Age in Surgical Prognosis

DR. ALBERT H. MILLER, Providence, R. I.: A study of 1,000 case records, classified as good, fair or poor risks, was made to establish the degree of danger attending operations on the aged. All patients recorded as good risks are expected to recover. Fair risks are operated on with less assurance, and major procedures are performed only when urgently required. In hazardous risks a high mortality rate is rather expected. The mortality rate in the cases of 271 patients over 50 years of age is eight times as great as in 729 persons less than 50 years of age.

(To be continued)

AMERICAN SURGICAL ASSOCIATION

Fiftieth Annual Meeting, held at Atlantic City, N. J., June 16-18, 1919

(Concluded from page 294)

Surgical Problems in Reconstruction of Peripheral Nerve Injuries

DR. CHARLES H. FRAZIER, Philadelphia: In our treatment of 550 cases at General Hospital No. 11, the proportion of cases in which operation was justifiable was 30 per cent. I observed the rule not to operate until three months after the wound had healed. In many instances, six months would elapse before the operation was undertaken. The great problem of peripheral nerve surgery is the bridging of defects after resection. Discarding as unworthy of consideration the flap method, tubulization, lateral anastomosis and suture distance, the surgeon must turn to nerve-stretching, nerve transposition, the position of the limb, the nerve transplant, and an operation for which I have coined the term "implantation suture." The latter is applicable in the arm, where a healthy nerve may lie in juxtaposition to the injured nerve, and differs from lateral anastomosis in that a portion of the healthy nerve is sacrificed. Tendon transplantation should be held in reserve for certain residual palsies, notably those of the fingers in musculospiral palsies and those of the feet in external popliteal palsies (foot drop).

Foreign Bodies in Stomach

DR. RANDOLPH WINSLOW, Baltimore: Multiple objects are swallowed either by the insane or by mountebanks. Practically all of these individuals come to operation sooner or later. I removed 1,290 different objects from the stomach of an insane woman. This, I believe, is the largest number of individual articles reported in the literature as having been removed successfully from the stomach of a living human being. The woman made an uneventful recovery. While many single objects pass through the intestinal canal and are safely extruded, multiple foreign bodies usually lodge in the stomach and require to be removed by gastro-tomy. This operation is a comparatively safe one and the percentage of recoveries is very high, even when the foreign bodies have remained in the stomach a long time.

DISCUSSION

DR. S. J. MIXTER, Boston: In a case seen in the operating room some time ago with a lump just above the umbilicus having the appearance of an abscess, incision revealed a quantity of yellowish pus which proved to be actinomycosis. The case was the first, I think, recognized in Boston as human actinomycosis. In this abscess were two large fish bones.

DR. WILLY MEYER, New York: Some years ago, before the advent of the roentgen ray, I was called to operate for what seemed to be a gastric condition. I found a large knitting needle sticking out of the stomach.

Operative Treatment of Peptic Ulcer

DR. JOHN B. DEEVER, Philadelphia: Other things being equal, excision of the ulcer or resection followed by gastro-enterostomy is the procedure of choice. Gastro-enterostomy of itself is a curative measure for a time, but to insure a positive result the ulcer must be removed. It has been my experience that a gastro-enterostomy properly made and properly placed, with a patulous pylorus, does not close. Resection plus gastro-enterostomy presents the same advantages as the less complete operation, with the added benefit of a direct attack on the ulcer. The proper time for medical treatment for the results of chronic indurated peptic ulcer is after and not before the operation, if treatment is then still needed. Carcinomatous degeneration of gastric ulcer is a menace which cannot be ignored. Probably nowhere does the personal equation of the operator enter more than in the operative treatment of peptic ulcers. In ulcer distant to the pylorus with very little exudative induration, simple excision may suffice. This applies also to saddle-back ulcers and those situated on the lesser curvature toward the cardia, for which circular resection is the indicated operation. From my experience on two occasions, I am becoming convinced of the advantage of following circular resection with a gastro-enterostomy. For perforation of a duodenal ulcer, I find it best after closing the perforation to plicate the duodenum and fortify the area by covering it over with the gastroduodenal and the gastrohepatic omentum and complete the operation with a posterior gastro-enterostomy.

Cancer of Stomach

DR. CHARLES H. MAYO, Rochester, Minn.: More than one third of the cancers in men and more than one fifth of the cancers in women appear in the stomach. From Oct. 1, 1897, to Jan. 1, 1919, 2,094 operations for cancer of the stomach were performed at the clinic. Seven hundred and thirty-six of these were resections, with a mortality of 137 per cent.; 746 were explorations with a mortality of 29 per cent., and 612 were palliative operations with a mortality of 11.1 per cent. For the last three years the anterior instead of the posterior Polya operation has been done in the clinic. Better after-results seem to be obtained by turning the bowel to the right, isoperistaltic, by closing the end of the stomach in toward the lesser curvature, and protecting the closed portion by suturing the unopened bowel over it.

DISCUSSION

DR. ARTHUR D. RYAN, Chicago: I am convinced that the great majority of gastric and duodenal ulcer patients can be cured medically and can be kept cured under proper after-treatment. With the opportunity of studying a large series of cases, surprising results of surgical management will be seen in recurrences after gastro-enterostomy for ulcer. I believe, however, that most medical men push the matter of medical therapy too far. An ulcer persisting after proper medical treatment is a surgical matter. The treatment of cancer of the stomach is as definitely surgical as is carcinoma of the breast. Within the last month I have resected three stomachs in which there was very early carcinoma. Carcinoma of the stomach is one of the most curable carcinomas in the body if it is early recognized.

DR. FRANK E. BENNETT, Cleveland: The curative result of a gastro-enterostomy is not to be measured by the immediate result of the operation, but such cases demand the most careful attention following the operation that can be given by the best medical men.

Abscess of Rectus Muscle Following Influenza

DR. HOMER GAGE, Worcester, Mass.: Next to empyema, the principal complication of surgical interest in the influenza epidemic at Camp Devens was a group of localized abscesses, most often periarticular and intramuscular, not involving the joints or any of the internal organs usually involved in metastatic processes. Of especial interest in this group were three cases of abscess of the rectus muscle.

They were first observed about a month after the onset of the pneumonia. Two patients had no other complication; a third had empyema and an abscess in the chest wall. Culturally all showed pneumococci, two Type I, one untyped. All patients recovered promptly after incision and drainage.

In the necropsy reports by Dr. S. Burt Wolbach, nine cases presented clearly defined Zenker degeneration of the rectus muscles with rupture of the muscle fibers and intramuscular hemorrhage. To a lesser degree the same process was observed in other muscles of the abdomen and in muscles of the chest. It seemed quite evident that these abscesses represented infected muscle hematoma and that the infection was blood borne. They presented themselves late in the disease, were not accompanied by manifestations of general sepsis, and were not readily diagnosed because unsuspected.

Lipovaccines for Immunization.—It is believed by Whitmore that the lipovaccines overcome some of the difficulties in the way of active immunization in public health work. The one great advantage of the lipovaccines is that the entire amount of vaccine can be given at one dose; and as the absorption is slow, the reaction is not marked, and the immunity response is at least as good as with saline vaccine. As the vaccine keeps for at least a year, it can be carried in stock for a reasonable time. Since it is possible to give a very large dose of bacteria in lipovaccine without severe reaction, it is possible to include two or more organisms in the single vaccine. While the lipovaccines have great advantage for use in protective inoculation, it does not appear that they are suited for use as therapeutic vaccines. In advising the use of lipovaccines, Whitmore says that it is necessary to guard against the danger of considering whether they allow of putting a large number of different organisms into one vaccine. One of the present dangers of bacterial vaccines is the tendency to include a large number of different organisms in one vaccine, without regard to whether there is any specific action on the part of such organisms. Whitmore discourages the use of "shotgun" vaccines, for the use of which there is no specific practical basis and for which the usual excuse is that they do no harm.

Pneumonia at Camp Bowie.—A large percentage of the 2,344 cases of pneumonia analyzed by Greenway and his associates followed an epidemic of influenza. Following the epidemic of measles, the predominance of hemolytic streptococcus as the infecting organism determined the high mortality and the high incidence of complications, especially empyema. Following the epidemic of influenza the incidence of hemolytic streptococcus was less, but when present the lesions produced did not vary from those present in cases of the year previous. In addition to the streptococcus infections there was a large group of cases of mixed bacteriology with pneumococcus, especially Group 4 predominating. Definite evidence of the presence of *B. influenzae* as a determining factor in pneumonias following the epidemic of 1918 was not obtained. Postmortem studies showed that the pneumococcus is constantly present in lobar pneumonia, while the hemolytic streptococcus, with a variety of other organisms, and the pneumococcus was found in the bronchopneumonia cases. Comparison of sputum examinations with more accurate bacteriologic data from the same cases, has shown correspondence in a large percentage of cases. Clinical differentiation between lobar pneumonia and bronchopneumonia to accord with postmortem findings has been impossible. For this reason it is suggested by the authors that the term acute pneumonitis, followed by a statement of the predominating organism in the sputum, be used to designate those cases of pneumonia which are not frankly lobar in type, but caused by one of the fixed types of pneumococcus. The incidence of empyema was highest among the pneumonias following measles. For the entire period, cases complicated with empyema constituted 10.6 per cent. of the total pneumonia deaths. The appearance of the pleural exudate caused by *Streptococcus hemolyticus* was characteristic. Repeated aspiration of such fluids, followed by operation after the acute pneumonitis had subsided, has given the more satisfactory results. The occurrence of encapsulated pus was very common, especially in the streptococcus infections. These pockets were frequently multiple and offered great difficulties from an operative standpoint.

Differentiation of Endameba of Amebiasis.—The point is emphasized by the authors that repeated successive examinations are essential to establish an adequate diagnosis and that flagellate infections are most readily detected in fluid stools after a saline purge, whereas the encysted phases of these and of the endamebas are more readily found in the formed stools of infected persons. The intermittent or rhythmic appearance of the encysted phases of the intestinal protozoa necessitates these repeated examinations to detect infections. Three successive examinations at intervals of several weeks are desirable in critical cases. All tests of cure after treatment should rest only on several repeated series of examinations to be conclusive.

Irritable Heart in General Practice.—According to Neuhof the irritable heart as observed in general practice is similar to that found in soldiers. Vasomotor symptoms are more pronounced in the former. The etiologic factors are similar, but because of training and war conditions, dormant and latent neuroses crop out oftener and are more readily evoked, consequently the cardiac syndrome is more violent and lasts longer. Infection is a factor only in so far as it induces and produces nerve and muscular fatigue and psychasthenia. There is no pathologic change in the cardiovascular system. The fundamental cause of the cardiac neurosis with its various manifestations seems to be due to hyperexcitation of the sympathetic nervous system.

Duration of Normal Convalescence.—Bridgman claims that he has made the first direct attempt to employ actual physical tests for the determination of the optimum period of convalescence, and that the periods determined seem so much longer than are generally employed.

Blood Uric Acid and Diet.—Baumann and his associates have carried out during the past three years about 180 renal dietary tests and blood analyses. Of 100 cases showing moderate and slight abnormality, respectively, all showed renal involvement from the clinical point of view. Sixty per cent. had an abnormality in the dietary test, while 74 per cent. showed an increased concentration of uric acid in the blood. It follows from this that the uric acid concentration of the blood is a delicate, if not the most delicate, index of renal function. An abnormal dietary test with normal blood findings was found in 8 per cent. of the cases. An abnormally high urea with a normal uric acid concentration was encountered in only six instances. The advantages of the bland diet are that it is easily prepared, and that it may be used where a high protein diet is undesirable or where digestive disturbances are present.

Suprarenals in Influenza.—The possible existence of disturbed function of the suprarenal glands as a cause of the asthenia present in all cases of influenza during the course of the disease and during convalescence led Cowie and Beaven to make an experimental investigation. The most common and the most marked symptom of suprarenal insufficiency is asthenia (prostration). Low blood pressure, another cardinal symptom of suprarenal insufficiency, has been commonly observed by clinicians as being characteristic of influenza and influenzal pneumonia. The authors endeavored to determine, on purely clinical grounds, if possible, whether a hypo-adrenia or a disturbance of the chromaffin system could be shown to be at the bottom of the symptom group so much in the foreground of this disease. Necropsy revealed hypoplasia of the suprarenals and evidence of suprarenal dysfunction. The occurrence of suprarenal dysfunction in influenza and influenzal pneumonia may be regarded as indicated by the cardinal symptoms, the characteristic rise in blood pressure following the prolonged administration of epinephrin, and the prolonged blood pressure curve following the administration of epinephrin. That an endocrinal disturbance is present in influenza and influenzal pneumonia is further suggested by prolonged blood sugar curve after injection of epinephrin. Hypoglycemia is not present in influenza and influenzal pneumonia as has been found to be the case in some diseases of endocrinal origin. However, therapeutic tests showed that if epinephrin is of any use in the treatment of symptoms of suprarenal dysfunction, the proper method of administering the epinephrin seems not yet to have been found.

Auscultatory Phenomena of Normal Heart.—A report is made by King of the various adventitious sounds and murmurs found in the examination of hearts of 500 supposedly healthy soldiers who had done army duty. A few unusual murmurs and sounds found in the examination of almost 1,500 supposedly healthy soldiers are recorded. King concludes that murmurs and adventitious heart sounds probably have only an accidental relationship to the "irritable heart of soldiers."

Influenza and Neurosyphilis.—The interrelation of coincident infections was studied by Menninger from the data presented by cases of neurosyphilis affected by attacks of influenza. Cases are cited to illustrate three effects of influenza on neurosyphilis: The precipitation of profound symptoms in previously latent neurosyphilis by influenza; the augmentation of symptoms and signs of neurosyphilis by influenza; the absence of palpable effect of influenza on the neurosyphilitic process. The latent, incipient, and early cases of neurosyphilis seem to be susceptible to precipitation or augmentation by the added neurotoxic effects of influenza; the advanced cases are not usually perceptibly altered in symptomatology or course. No instances of improvement of neurosyphilis following influenza were observed by Menninger. The scanty literature is collected and epitomized.

- *Pernicious Anemia with Mental Symptoms. L. A. Lurie, Cincinnati.—p. 67.

Central Neuritis.—A thorough histopathologic study in two cases of "central neuritis," and many other cases were made by Marui. Almost all the Betz cells in both cases and some cells of the spinal cord of the first case showed the typical axonal reaction; in the first case the fiber alteration was superimposed on this picture. Fragmentation of the intracellular neurofibrils was found in the glassy area. The alteration of neurofibrils keeps pace with the dissolution of the Nissl bodies. Besides Marchi impregnation of myelin sheaths, a very interesting picture of axis cylinders was disclosed. Ameloid glia cells showed the Alzheimer tuchsinophil granule, a finding which indicates an increased scavenger activity of the neuroglia tissue. In two cases of central neuritis and many other cases in ameloid and preameloid glia cells, on the one hand, and in case of hemorrhage in granule cells on the other hand, a new "nucleoprotein-like granule" was demonstrated. The author concludes that neuroglia has a constructive function besides a scavenger function, and that this granule is given the neuroglia cells in an afferent direction.

Epidemic Encephalitis.—The pathologic changes in epidemic (lethargic) encephalitis found by Bassoe and Hassin involve the entire central nervous system. These changes are both parenchymatous and interstitial. The former principally involve the cortex, the latter the peduncles, internal capsule, lower pons, bulb and cord. In the basal ganglia and midbrain both parenchymatous and interstitial changes are pronounced. In its histopathology epidemic (lethargic) encephalitis differs from the various types of hemorrhagic encephalitis, but it is identical with that of African sleeping sickness (trypanosomiasis). It differs from typical cases of paralytic dementia by the topography of the lesions and by absence of vascular wall changes, which probably are due to the more chronic course of the latter. It also differs from the various types of traumatic and experimental encephalitis and from acute anterior poliomyelitis. It is pathologically a distinct morbid entity, a disease *sui generis*, and does not resemble the conditions previously described as influenzal encephalitis. The similarity between the pathologic changes in African sleeping sickness and epidemic encephalitis suggests a close relationship of their etiologic factors, that is, the epidemic encephalitis may be caused by a parasite akin to a trypanosome.

General Paralysis Treated by Intraventricular Injection of Arphenamin.—Sands claims that this is the first case which has received this form of therapy and has been studied clinically as well as at the postmortem. The patient was a man, aged 40, who had one living child, a negative family history, but an alcoholic personal history, who had no knowledge of any venereal disease. He began to show lapses of memory in December, 1915, which increased in severity so that he was obliged to discontinue his work in the middle of 1916; he then became irritable, showed speech defect and became ataxic; in March, 1917, he received one intraventricular injection of arphenamin through a trephined opening in the skull. May, 1917, he showed disorientation, poor memory, expressed grandiose ideas; showed marked speech defect, pupils were unequal and reacted very sluggishly to light, and the spinal fluid showed positive globulin, fifty-four cells, and a positive Wassermann reaction. He soon began to soil himself, became very euphoric and died following a convulsion. The postmortem examination showed the characteristic lesion of general paralysis in the brain; namely, a thickened

pia showing a characteristic milky exudate in the anterior two thirds, atrophy of the anterior poles of the cortex, lymphoid and plasma cells infiltration into the pia, neuroglia increases, cortical disorganization and perivascular exudation of lymphoid and plasma cells, many mast cells and a few rod cells, granulations on the floor of the ventricles, syphilitic aortitis and bilateral bronchopneumonia and pulmonary edema; the lesions in the left side of the brain which received the arphenamin were more intense than those on the right side.

Treatment of Neurosyphilis by Arphenamin Intravenously and Auto-Arphenaminized Serum Intraspinaly.—In this series of twenty-one cases, 214 intraspinal treatments were given by Goodwin and Scott. Severe reactions have occurred, but no permanent injury or ill effects resulted from the intraspinal use of auto-arphenaminized serum. The treatment has uniformly been of benefit in its effect of increasing the patients' comfort by lessening the severity and frequency of their pains, in frequently improving bladder control, and in improving their nutrition. Improvement in station and in gait has frequently been observed in these cases, and in some, to a very marked extent.

Pernicious Anemia.—In speaking of the neuropathology of pernicious anemia, Lurie says it is not sufficient merely to describe the lesions found in the spinal cord. The brain changes are too numerous and definite to be omitted. The neuropathology of pernicious anemia should include the entire central nervous system. He records the findings in four cases.

- *Ulcerative Granuloma of Genital Organs. S. Gudián.—p. 53.
- *Blunders in Diagnosis. A. Martínez Álvarez.—p. 55.

Prostitution from Sociological Standpoint.—Atiles reports the detailed study of the reasons for taking to prostitution in 168 cases, and compares his findings with those that have been published by others. Nearly 5 per cent. of the women were of illegitimate birth, and only eighteen of the total 168 were able to read and write, although some of the others had attended school. His conclusions confirm those of others in regard to prophylaxis of prostitution as inevitably connected with uplift movements in general, economic, educative, biologic and legislative.

Epidemic Meningitis.—Igaravidez reports four cases of epidemic meningitis. He claims that the first case mentioned was the first instance of the disease known in Porto Rico, and that the case was published in THE JOURNAL A. M. A., Dec. 21, 1918, under the title "Early Diagnosis of Cerebrospinal Meningitis by Examination of Stained Blood Films." Two of the patients were children, and the others were women, one the mother of the second child. The last three cases all occurred in May, 1919. The infection was of such a fulminating type in two of the cases that death occurred before the meningitis had had time to develop. In all the cases meningococcus sepsis was evidently responsible for the fatal termination. The diagnosis was made in each case from the blood films, and he urges examination of blood from a finger tip as an early routine measure, making from four to six slides and taking the blood count. The discovery of the meningococcus in the blood may render it possible to give the antiserum in time to ward off the invasion of the meninges. He mentions Laveran's statement that cerebrospinal meningitis is a winter disease, dying out in the summer, and that its range is from latitude 60 N. to 36 S.

Epinephrin in Typhoid.—Barreiro says he has only twenty odd cases to report, but the benefit from epinephrin treatment was so great that he does not wait for further experience before proclaiming the advantages of suprarenal treatment in typhoid in the tropics. The benefit from epinephrin in the exhaustion of the soldiers in the trenches was mentioned early in the war, and he was impressed with the similarity between the conditions as described in this war

exhaustion from overwork and the exhaustion of patients early in typhoid. This suggested suprarenal treatment in typhoid, as the patients are often in an exhausted condition from the cares and work of business or from late hours and dissipation. He adds that the food in the tropics is too often defective and inappropriate, so that dyspepsia and liver disease are more prevalent in Porto Rico than among the soldiers in the trenches, as the diet of the latter was more rational than is the custom in the tropics. The perpetual summer climate promotes intestinal fermentations and auto-intoxication. The suprarenals soon become unequal to their task, as is evident from the intense weakness and low blood pressure early in typhoid. The theoretical indication to supply the lacking suprarenal element was abundantly confirmed by the prompt improvement under suprarenal treatment. In a day or two the benefit was plainly evident, the patient feeling stronger, replying lucidly to questions, and the amount of urine increasing while it grew more normal in appearance. It was an actual resurrection in some cases by the second day after 3 drops of the 1:1000 epinephrin had been given by the mouth in a glass of water, twice a day. The improved muscle tone was particularly evident in the tongue which at first was not under control at all. The epinephrin was continued until deconvalescence in one case described in detail. After suspension for four days, the pulse ran up to 120. An immediate injection of 0.5 c.c. of the epinephrin solution corrected this, and convalescence continued without further mishap. In another case the fever kept up for thirty-three days, but the epinephrin tided the patient along into convalescence. There was no tendency to intestinal hemorrhage in any of the patients given the epinephrin. Another feature of epinephrin treatment is that the stools lose their diarrhetic character; the epinephrin passing through the alimentary canal seems to induce vasoconstriction and thus checks the tendency to diarrhea and averts danger of hemorrhage. Since he began this routine use of epinephrin in tropical typhoid he has not lost a case.

Ulcerative Granuloma of Genital Organs.—Guiliani reports the first two cases in Porto Rico in which *Bacterium granulomatosis* has been cultivated from a granulomatous lesion on the genital organs. He adds that these lesions in the past may have been mistaken for syphilis or cancer.

Blunders in Diagnosis.—As already mentioned in THE JOURNAL, April 26, p. 1253, Alvarez is inaugurating a series of confessions of blunders in medical practice. He opens the series himself and relates three rather mortifying experiences from his earliest year of practice, although none were exactly blunders.

Temperature Variations in Infancy and Early Childhood.

—Abt lays emphasis on the fact that temperature observations in newly born and young infants have not only scientific interest but a clinical bearing. The proper interpretation of the temperature fluctuations in infants is of fundamental importance, but like other fundamental phenomena is rarely emphasized. The peculiar levels and irregular temperature curves in young infants should be recognized. Changes in temperature in infants have not necessarily the same significance as in adults. Sudden high temperatures in newly born infants are of frequent occurrence. Abt says that he has been able to follow many children through infancy and childhood who thrive and seem to be in perfect health and constantly show a temperature of 99 F., 99.5 F. and even 100.5 F.

Studies in Diphtheria Toxin.—Davis and Ferry were unable to cultivate *B. diphtheriae* in a synthetic medium composed of amino-acids and mineral salts adjusted to the optimum H-ion concentration. Addition of the extractives, creatin and creatinin and the purine bases, xanthin and hypoxanthin, was of no advantage. Typical luxuriant growth of *B. diphtheriae* was obtained in a mixture of 99.5 per cent. synthetic medium and only 0.5 per cent. of bouillon. Production of active toxin, however, required the presence of 10 per cent. bouillon. Cystin, when added to plain beef infusion, a culture medium just capable of maintaining growth of *B. diphtheriae*, not only permitted rapid and heavy vegetation, but a strong toxin (minimum lethal dose equals 0.0075 c.c.) was also elaborated. This appears to be a true toxin capable of neutralizing the corresponding diphtheria antitoxin. The results obtained favor the belief that diphtheria toxin is not a synthetic product, but rather a catabolic substance elaborated by *B. diphtheriae* only in presence of certain amino-acids and accessory factors, in the latter probably of a vitamin character.

Iodin and the Thyroid.—Swingle offers further evidence in support of the theory that the thyroid is an organ the function of which is the extraction from the circulation, storage and supplying to the organism, under the pressure of its needs, the small quantities of iodine taken into the body. The chief function of this gland, then, is the utilization of iodine taken into the body in small quantities.

War Surgery and Industrial Surgery. J. J. Moorehead, U. S. Army—p. 158.

Mortality from Unhealthy Trades.—From an analysis of all the data available Reiley concludes that the actual mortality from chronic lead poisoning is small, even making all possible allowance for dilution of exposures by lives not dangerously in contact with the poison. Painting is not so dangerous a trade as working directly in lead compounds, as occurs in white lead works, glaze rooms in potteries, smelting and tanning work, and storage battery plants. Miners' consumption ranks on a par with lead poisoning as the most dangerous disease. This disease is principally dangerous when the mining is done in siliceous ores. In this, as in lead poisoning, the actual rise in mortality must be looked for from other immediate causes than miners' consumption, principally from tuberculosis and pneumonia.

Inhalation of Dust.—Landis points out that it is not always easy to differentiate between the fibrosis resulting from tuberculosis and pneumoconiosis and were it not for repeated negative sputum examinations, sometimes extending over a number of years, it would not be easy to say that tuberculosis was not present. The clinical history of pneumoconiosis is reviewed in detail.

Back Strain: Accident or Disease.—The question asked in the title is answered by Osgood in this way: either, or neither, or both. He says that unless the most careful examination is made, and unless the most accurate diagnostic methods are employed, physicians will continue to be puzzled by the persistence of the symptoms and patients will continue and often obtain osteopathic, chiropractic and nostrum relief. Forceful manipulation is not without danger nor is a back brace a panacea. The diagnosis of hysterical spine should rarely be made. The diagnosis of railroad spine means nothing. The diagnosis of functional spine is usually a confession of ignorance of the true cause of the trouble. Each case should be analyzed, and also a knowledge of the normal and the commonly symptomless variations is needed.

Chronic Endometritis.—As a result of the study of a large number of uterine curettings, Schwartz and Kohlbrly feel that chronic interstitial endometritis is rather frequently encountered. Their cases included many cases with neither history of inflammations or with clinical inflammatory findings, and many were cases of incomplete abortion. The number of small round cells in the early premenstrual, late postmen-

strual and interval phases is never very great, and their arrangement does not correspond to what is found in a chronic inflammatory process. The authors feel that the presence of small round cells alone in marked numbers, as was the case in twenty-four instances of their series, is sufficient evidence on which to base a diagnosis of chronic interstitial endometritis.

Rest in Tuberculosis.—An abstract of this paper will be published soon in *THE JOURNAL* as a part of the report of the meeting of the American Therapeutic Society.

Subcutaneous Ether-Oil Anesthesia for Guinea-Pigs.—Many animals during the war were required in both medicine and surgery in the effort to conserve the life of the soldier. The blood of guinea-pigs and rabbits was used extensively in the production of reagents for the Wassermann reaction, and the blood of rabbits was used in the production of diagnostic serum. Dogs and cats and in the decision of many problems concerning the badly wounded soldiers, such as shock, or the choice of one of several operations. It is desirable to anesthetize these animals in the most humane, the simplest, quickest and safest way. These requirements have been met by the subcutaneous injection of ether and oil. After various modifications, the technic, as finally employed, consisted in giving the injection just back of the neck, against the direction of the hairs, which are not removed. The following doses have been determined for guinea-pigs: For each 100 gm. of body weight, 85 per cent. ether with 15 per cent. olive oil was the mixture used in the experiments. Maximum safe dose—anesthesia of one to two hours: 0.74 c.c. of ether, or 0.87 c.c. of 85 per cent. ether and 15 per cent. of oil mixture (or 1.00 c.c. of 75 per cent. ether and 25 per cent. oil

mixture). Medium dose—anesthesia for about one hour: 0.55 c.c. of ether, or 0.65 c.c. of 85 per cent. and 15 per cent. oil mixture (or 0.72 c.c. of 75 per cent. ether and 25 per cent. oil mixture). Minimum practical dose—anesthesia of about thirty minutes: 0.46 c.c. of ether, or 0.54 c.c. of 85 per cent. ether and 15 per cent. oil mixture (or 0.60 c.c. of 75 per cent. ether and 25 per cent. oil mixture).

Cerebrospinal Findings in Influenza.—This report is based on twenty-five typical cases of influenza, the patients ranging from 7 to 42 years in age. In all cases an increase in the pressure of the spinal fluid was noted. This varied from a strong full stream to a rapid flow of drops. The first important point of interest noted was the clearness and translucence of the fluid; in no case was the fluid turbid or cloudy. The globulin reaction of Noguchi was strongly positive in all; a flocculent precipitate showing immediately on adding the sodium hydroxide solution. A constant deep canary yellow color was present in performing this reaction, just before the precipitate was formed, and on forming the color would disappear entirely. The reduction of Felling's solution was present in a marked degree. The cell count was found to be low. In one case it was over forty to the cubic millimeter. Differential count of cells showed a predominance of polymorphonuclear cells over the lymphocytes, although disintegration of these cells was marked. No organisms were found after rapid centrifuging of smears made from the fluid. Of the twenty-two cases studied, eighteen showed a positive culture. All of these cases ended fatally, except one. Spinal fluid cultures revealed the presence of a characteristic organism in a large proportion of the cases. The organism is a bacillus, gram-negative, facultative anaerobe, nonmotile, acid producing, and forms spores. The organism was found in 81.8 per cent. of the cases studied. This organism is different from any heretofore isolated from the spinal fluid.

- Helping the Backward Child. F. W. Barrows, Albany.—p. 284.

Etiology of Pneumonias.—The chief point brought out by Cole is that in considering the etiology of pneumonia one cannot consider only the pathogenic micro-organisms. Many other factors must also be taken into account. In few cases of pneumonia, possibly in none, does the disease occur simply because the pathogenic micro-organisms gain access to the lung. A person suffers from pneumonia as he does from other accidents, through a combination of circumstances. Moreover, epidemics also arise when a proper combination of circumstances occur. By focusing attention on one factor alone, the explanation sought for may be found.

Treatment of Influenza.—Lambert says that in the general treatment of the patient with influenza, there seems to be no question that the salicylates and salicin relieve the distressing ache and pain. Ammonium salicylate and ammonium carbonate, in 5 grain doses, every two hours, seem materially to produce this result and to produce a not excessive sweating with the reduction of the temperature. It is in the pneumonic congestions of influenza type that ergot seems to be of use in reducing the congestion and bring about a better circulatory equilibrium. If not given hypodermically, a mixture of the extract with the extracts of nux vomica and gentian, one-half grain each, every two hours, often seems to produce a good effect. The persistent spraying of the nose and pharynx with some form of silver salt, or some form of mild disinfectant materially aids in confining the infection, in its early stages to the upper passages, and this procedure gives the impression, when tried in a large number of patients, that it prevents in many cases the spread downward into the bronchi and thus limits pulmonary complications.

Results of Preventive Vaccination Against Influenza.—

Wadsworth reports on the use of influenza vaccine in New York state comprising scattered reports from different physicians and health officers, general reports from all the state institutions, and report of special selected institutions. The vaccine was prepared by suspending in physiologic sodium chlorid solution the growth of fifteen different strains of the influenza bacillus on the surface of a coagulated blood glycerin veal agar. One c.c. contained one billion bacilli. Summing up the results of this study as to the practical value of vaccines in influenza, it is evident that the vaccines that have hitherto been used have failed to give reliable protection against influenza or influenzal pneumonia.

Kidney Function in Disease.—This paper attempts an understanding of kidney functions in disease and an explanation of the symptoms involved, basing such attempt on the modern theory of kidney secretion and on the facts of kidney pathology so far known.

Ovary and Corpus Luteum Extracts.—The action of fresh and desiccated ovary and corpus luteum was studied by Matsumoto and Macht on the bladder, uterus and fallopian tubes, vas deferens and seminal vesicles of various animals. Corpus luteum extracts have very little effect on the contractions and tonicity of the excised bladder or ureters. Corpus luteum extracts exert a very stimulating effect on the excised uterus and fallopian tubes, but their action on these organs is not specific as the same effects are produced by administration of extracts of all kinds of glands. Corpus luteum extracts exhibit a markedly stimulating action on the excised vas deferens and the seminal vesicles are stimulated by doses of corpus luteum extracts. In respect to their effect on all the genitourinary organs studied, ovarian extracts exert a very much weaker action than corpus luteum extracts. The peculiar and sensitive reaction of the vas deferens of the rat to the effects of corpus luteum extracts is, physiologically speaking, proportional in intensity to the doses of the drug used, and runs parallel to the effects of the same extracts on the blood pressure and on the pupil of the frog's eye. It, therefore, offers a convenient method for the assaying of corpus luteum preparations on the one hand, and for the testing of physiologic activity of various chemical derivatives of the corpus luteum on the other.

Fish Poisoning in Persian Gulf. C. C. Kelly.—p. 215.

Viper Poisoning.—The treatment now recommended for snake bite poisoning according to Coffin, consisting of the intravenous injections of Bayliss' fluid (gum arabic, 7 parts; sodium chlorid, 0.9 part; water, 92.1 parts), injection of epinephrin and the intramuscular injection of 1 gm. of calcium chlorid with 20 minims of water, is not intended to supersede the administration of antivenene, which should always be injected in cases of viper poisoning, known to be due to Russell's viper or of dubious origin. The treatment is intended as an adjunct to cases known to be due to Russell's viper, and should prove extremely valuable in cases of echis poisoning, there being no available antivenene for the treatment of these cases.

Vaccines in Cholera Prophylaxis.—Roy says that vaccination against cholera has been proved to be so highly efficacious in the army and labor corps as to warrant its extensive use as a prophylactic measure among the civil population during an epidemic, or when cholera is likely to break out. It has been found efficacious in the Japanese epidemic of 1902, in the Russian epidemic of 1908-1909 and in the tea districts in Assam. In the recent war, the beneficial effect of prophylactic inoculation had been proved by Hoffman in the German army and by Kaup in the Austro-Hungarian army. The new cholera vaccine of Kasauli is the result of various experiments done from time to time. It combines the efficiency of Hafkine's vaccine with no local or general reaction at all. It consists of a pure, sterilized culture of cholera spirillum absolutely free from any reaction (local or general), and can safely be injected into people of both sexes, of all ages, including infants, and in all stages of health, including pregnant and recently delivered women.

Latent Sinusitis in Relation to Systemic Infections.—Two cases are cited by Watson-Williams, one a case of rheumatoid arthritis with chronic catarrhal deafness, and the other a case of rheumatoid arthritis with appendicitis, etc. He believes that these cases prove that a latent sinus infection may persist for a great many years, that chronic rheumatoid arthritis and other infective rheumatic symptoms may be due to a sinus infection and that appendicitis may be due to infection through the gastro-intestinal tract from a nasal sinusitis. The previous history of nasal sinusitis cases is worthy of careful note. Wilson also suggests that some cases of systemic septic infection attributed to tonsil infec-

tion may be due to a nasal sinusitis which has caused the tonsil infection with hypertrophy of the tonsil lymph tissue.

*Case of Multiple Osteoma of Skull Bones. C. N. Stanley.—p. 13.

*Case of Congenital Multiple Sarcomatosis. J. A. Perera.—p. 14.

Case of Cirroid Aneurysm of Palm of Hand. J. Toledano.—p. 15.

Eye Color and Abnormal Palate in Neuroses and Psychoses.—Gordon attempts to show that in individuals who are susceptible to the neuroses and psychoses duplex eyes are more than twice as common as simplex eyes. In the same class of individuals the abnormal and arched palate is present in about 52 per cent. of cases. In the same class again, the proportion of duplex to simplex eyes is markedly increased in those cases with narrow and abnormally arched palates, and the increase tends to intensify along with the intensification of the palatal abnormality.

Uncommon Abdominal Cases Illustrating Some Pitfalls.—Kevin reports a case of traumatic diaphragmatic hernia, one of internal hemorrhage from a splenic infarct and a case of acute idiopathic dilatation of the stomach.

Congenital Multiple Sarcomatosis.—In Perera's case multiple rounded and nodulated tumors were scattered throughout the body, e. g., head, thorax, abdomen, upper and lower extremities. These tumors, present from birth, were of varying sizes. There was superficial ulceration in the larger tumors; one or two on the cheeks and legs had started to fungate. The consistence ranged from jelly-like softness in the more superficial ones to more or less bony hardness in the tumors attached to the long bones, ribs and skull.

Psychoneuroses of War. W. R. Regnell, Adelaide.—p. 455.

*Blood Culture in Summer Diarrhea. R. Webster.—p. 460.

Blood Culture in Summer Diarrhea.—Of eleven cases in which blood was noted in the stools, five yielded a positive result in blood culture and six were sterile. Of sixteen other cases, all were sterile or gave a few colonies of *S. albus* only. The several strains isolated from the first three cases conform morphologically, culturally and in their biochemical reactions to *B. faecalis-alkaligenes*. In each instance the organism recovered possessed the following attributes of *B. faecalis*: motility, negative reaction to gram stain, a thick, moist growth on agar-agar, inability to ferment glucose, lactose, saccharose, dulcitol, sorbitol and mannitol, and the property of inducing alkali formation in litmus milk. Its presence in the circulating blood is of particular interest in view of the fact that *B. faecalis-alkaligenes* is not commonly credited with pathogenic power.

*Radiosusceptibility of Suprarenals. A. Zimmermann.—p. 791.

Chlorination of Water.—The five models of portable apparatus used by the French for sterilizing the drinking water for the troops at the front are described and compared. The working of the apparatus was in charge of the laboratory of the medical department, and all the types used proved satisfactory except for waters containing much clay, as this absorbs the chemicals. These portable apparatus are particularly to be commended for small communities and for colonies.

War Deafness.—See Paris Letter, p. 208.

Pathogenic Fungus in War Wounds.—The fungus isolated by Sartory from the pus in one case was of the *Scopulariopsis* genus and proved extremely pathogenic for rabbits and guinea-pigs. He describes it as a new species.

Glycosuria in Meningitis.—Glycosuria seems to be rare in meningitis. De Massary and Tockmann discovered it in 3 of 45 cases. Cazamian in 3 of 9, and Loeper in 1 of 7. In the 3 cases reported in detail the meningitis had become partitioned off in the ventricles; the antiserum by lumbar puncture failed to reach this ventricle focus, and the men died. As these seemed to be the only ones with this involvement of the ventricles, and as these were the only ones with glycosuria, the inference seems justified that the glycosuria was a warning signal that the disease had invaded the ventricles. The irritation from this acted like the sugar puncture of the third ventricle. Trephine puncture of the ventricles thus seems the logical indication with glycosuria in meningitis, judging from the necropsy findings in these 3 cases. The glycosuria is not inevitably a sign of malignant course, as Cazamian had only one death in his 9 cases of glycosuric meningitis.

Treatment of Strabismus.—Sauvigneau affirms that the deviation of one or both of the eyes is only a secondary symptom of strabismus. The essential disturbance with strabismus is inability to focus the lines of vision on the object, and this, he insists, is the result of an anomaly in the perceiving centers in the brain. Only the visual image from one eye alone is perceived. The cross-eyed are cerebrally blind of one eye. Both eyes may be visually perfect but the brain perception is monolateral; the brain neutralizes or drops out the image furnished by the deviated eye. Treatment should consist in training the brain centers to bilateral vision; the deviation of the eyeball will then usually correct itself spontaneously. He accomplishes this with glasses of complementary colors, green for one eye and red for the deviated eye, through which the subject looks at the flame of a candle through a hole in a screen. At first he sees only the green flame, but by shutting off the eyes alternately he sooner or later finds that he can see a red flame along with the green. This diplopia is converted into normal vision of one flame (theoretically white from the fusion of the two complementary colors), by having the subject relax or contract his convergence, guided by the red and green luminous points. If the strabismus is mild, he soon succeeds in this fusion of the two luminous points into one. Sauvigneau has thus conquered strabismus of 30 and 40 degrees in less than three months. With these pronounced cases, it is better to graduate the efforts by the aid of prism glasses. With a prism glass properly placed, the green and red images are brought closer together till they are only a few centimeters apart and the subject easily fuses them. Then weaker prisms are used until binocular vision is reestablished. He declares that a cure can be realized in every case by this simple means (amblyopia is not an obstacle), which can be applied by any practitioner. Of course the procedure succeeds only with true strabismus, not with insufficient convergence from latent diplopia. The tendency to true strabismus seems to be inherited, and the slightest obstacle to binocular vision is enough to bring it on.

Röntgen Treatment of the Suprarenals.—Zimmermann has succeeded in making röntgen exposures of the suprarenals and thus inducing histologic modifications in animals and

functional changes in man, without any appreciable by-effects in skin or kidneys. In the clinical cases of hyperfunctioning of the suprarenals, with high blood pressure, the pressure dropped in every case in from two to ten days, and the drop ranged from 2 to 8 cm. The blood pressure kept at this lower point for a shorter or longer period, up to several months in some.

- *Tracheobronchial Glandular Disease. H. Méry and others.—p. 471.

Chronic Nephritis.—Merklen and Desclaux recently re-examined twenty-six men who had been temporarily dismissed from the army a year before on account of kidney disease. There could be no question of a cure in 77 per cent, but treatment had seldom been systematic. In only 35 per cent. of the cases of definite nephritis was the course evidently progressive; in the others the condition had improved or was stationary. The most favorable cases were those of acute chloridemic nephritis, which is the most common form of nephritis in soldiers. That a complete cure of chronic nephritis is possible is demonstrated by two cases of chronic recurring nephritis in men of 49 and 32 given thorough treatment and cured since 1909 and 1915, after the nephritis had returned two and three times in the course of five or six years.

Chemistry of the Fasting Stomach.—Labbé relates that the fasting stomach contained fluid in 91 per cent. of 109 cases of dyspepsia but only in 5 per cent. was the fluid left over from the last meal, with food detritus. With hyperchlorhydria there was manifest gastroenterorrhea in a third of the cases; in the others there was less than 30 cc. of fluid. With hypochlorhydria or anachlorhydria, fluid was constant, over 100 cc. in some cases. With normal gastric juice, there was almost always 30 cc. of fluid or more in the fasting stomach of dyspeptics. The secretion of gastric juice was sometimes retarded. It is possible that certain cases of gastric ulcer classed as hypochlorhydria when examined one hour after the test meal were in reality retarded hyperchlorhydria. This would explain the tardy pains in these cases of assumed hypochlorhydria. The variations in the chlorhydria, he adds, depend essentially on the free hydrochloric acid of the gastric juice. In his study of numerous cases in soldiers in his service, the evolution of the dyspepsia was mirrored in the chemical findings in the fasting stomach. As the condition improved, the chlorhydria veered to normal. The persistence of abnormal findings indicates a grave prognosis.

Claude Bernard Syndrome with Goiter. In the case described by Jacob the large goiter in a woman of 30 compressed the trachea and the sympathetic nerve, and the oculocardiac reflex was exaggerated.

Gastric Syphilis. Galliard and Mendelsohn emphasize that the prompt recovery under specific treatment is sometimes the only means of differentiating a syphilitic affection of the stomach. In the case reported, a man of 55, thirty-three years after he had contracted syphilis, developed hyperchlorhydria and painful dyspepsia with profuse diarrhea but no signs of syphilis, no melanin nor appreciable tumor, and the stomach was free from adhesions, but radioscopia showed a kind of strangulation which suggested cicatricial tissue. This disappeared however in less than a month, along with the gastro-intestinal disturbances, under mercurial treatment.

Influenza in Infants. Achard and his co-workers review thirty-two cases of influenza in infants with or without complications on the part of the air passages. Eight of the thirty-two infants died; the disease was well under way when the children were brought to the hospital. The influ-

enza was of the same three types as in adults, simple, with bronchitis, or with pneumonia. They describe each case in full as a contribution to the better knowledge of influenza in infants. No difference in its course in breast-fed infants could be detected.

Relapsing Measles.—Desbouis reports an epidemic of 30 cases of measles, in which in 7 a typical new eruption developed the sixteenth, thirteenth or twenty-seventh day after the first eruption. The type of the epidemic was severe, 3 of the 30 cases terminating fatally. Oculonasal catarrh accompanied each eruption. This with the other findings he accepts as testimony against the possibility that the second eruptive disease might have been rubella.

The Radiologic Findings with Disease of Glands at the Hilum.—Méry with his collaborators class these *adénopathies hilaires* by the roentgen findings in three groups, as they show by illustrated summaries of fifteen cases in children. The three types of findings may be observed in turn in the same child, all starting in the hilum, close to the sternum in the first three interspaces, and running a slow course, with persistence of the physical signs and tending usually to recovery. There is evidently an inflammatory process in the ganglia of the hilum inducing reactions in the neighboring tissues. They have encountered cases of this kind more often since the pandemic of influenza. This may have reactivated dormant processes. In the discussion that followed, Rist emphasized that the fact of retrogression of the lesion does not exclude the possibility of the lung having been involved in the process.

June 7, 1919, 9, No. 23

- *Postfebrile Alopecia. R. Sabouraud.—p. 437.
- Postvaccinal Trichophytosis. Gougerot.—p. 442.
- *Of Dermatitis. P. Blum.—p. 445.
- *Syphilitic Vitiligo. A. Touraine.—p. 451.
- Factitious Phlegmon of the Hand. Burnier and Bandoi.—p. 456.
- Fatal Pyosepticemia from Furuncle. Blanc and Colombe.—p. 457.
- *Tubes from Inherited Syphilis. A. Galliot.—p. 462.
- Duret's Universal Prophylactic Salve. G. Midan.—p. 464.

Postfebrile Alopecia.—Sabouraud remarks that he does not know of any thorough study of this subject that has been published. It has been his experience that a diffuse, general and sudden falling of the hair can be traced to some febrile state from sixty to eighty-five days before in which the temperature passed 39.5 C. (103 F.). The falling of the hair seems to be proportional to the height and duration of the fever. The hairs keep dropping out for from four to six weeks, but they do not all fall, and they grow again in a few weeks. The longer hairs drop out first. These rules apply without exception, he says, to all cases. The physician can confidently reassure the woman that she will not become entirely bald; and that her hair will grow again and this very soon. She can have a switch made of the hairs that have dropped out, but there is no necessity for a wig as the hair will soon grow again. Sabouraud protests against the practice of cutting the hair to aid in its regeneration. There is no logical basis for this as he explains; grass grows better when it is cut, but this cuts the head of the grass while the head of the hair is in its follicle. If frequent cutting made hair grow better, men would have better hair than women. He reiterates that women never grow bald like men, and that the difference between the mentality of men and women as it has developed through the centuries is shown more strikingly than anywhere else in the way they regard the falling of their hair. The hair will grow again as before if the scalp is healthy. Friction massage (preferably with a tooth brush) and tonic lotions with a gentle revulsive action giving ten minutes daily to this for a woman, four minutes for a man, are all that is necessary. If the scalp is not healthy, it should be treated according to indications. Sabouraud remarks parenthetically that seborrhea seems to be connected in some way with the adult development of the sexual organs. Eunuchs never have seborrhea and never become bald. A seborrheic woman loses the seborrhea when she becomes pregnant, and her hairs do not drop out in the same way, but after delivery the seborrhea returns. There is no appar-

ent relation between the excessive or the nonuse of the sexual organs and the seborrhea.

Oil Acne.—Blum gives an illustration of the dermatitis observed in workers in munitions and cloth factories, etc., where lubricating oil is used in abundance. Oil-mixed metal or cotton dust obstructs the follicles and the result is an occupational folliculitis, a crop of "oil pimples."

Syphilitic Vitiligo.—Touraine urges the necessity for seeking syphilis in every case of vitiligo, and he emphasizes the frequency of meningeal reactions with vitiligo. He has compiled 39 cases of nervous affections, from hemiplegia to tabes, in the course of vitiligo, but it is only recently that the spinal fluid has been examined in this affection. In 24 of 37 cases the spinal fluid was abnormal. In 81.1 per cent. of all cases of vitiligo examined, the patient proved to be syphilitic. It seems to be due to a trophic radiculitis.

Tabes from Inherited Syphilis.—In Galliot's two cases the inherited syphilis had been absolutely mute in one; the tabes developed at 29 and 36. The uneven pupils in one case had been noted from childhood but vision was normal; under treatment of the tabes the pupils became symmetrical. In both, the tabes developed under the stress of the campaign.

*Hot Saline by the Vein in Shock from Hemorrhage. C. Dunet.—p. 323.
*Arsenic Content of Neosphenamin. G. Dupont.—p. 324.

Resection of Elbow.—Leriche has recently resected twelve men who required subcapular-periosteal resection of the elbow for suppurating osteo-arthritis after a war wound. He followed Ollier's technic, and reports that the ultimate results over two years afterward are remarkable from every point of view. Some of the cases illustrated show perfect functioning of the elbow. The intrafascial resection of the infected joint was done from eight to fifteen days after the wound. Patience and perseverance on the part of both surgeon and patient are indispensable, but few operations on an infectious focus give such satisfactory final results to the patient himself and to those who have been tending him. Leriche's roentgenograms show the workings of the new joint. The head of the radius often becomes regenerated with surprising perfection. He begins to mobilize the joint in two weeks, doing it himself and very gently, and teaching the patient to use the joint himself, without abrupt movements. Heliotherapy was applied when possible, and recuperation was almost integral in some of the cases.

Radiotherapy of Tuberculous Arthritis.—Briton gives the details of three cases to confirm the superiority of roentgen treatment in certain cases of tuberculous arthritis. The tuberculous processes were in the ankle and astragalus, the elbow or the lumbar vertebrae, and the patients were two young women and a man of 28. The vertebral process in the man had been curreted two months before and the focus was still suppurating and spreading. The process was given roentgen exposures every two weeks at first and with longer intervals later. Each dose was about 4 H with 1 mm. aluminum filter at first and later 2 mm. The exposures were given for six months in all, and the cure has been apparently complete since 1912 or 1913 in each case. The process in the elbow of the woman of 27 had been curreted three times in the course of five years but kept recurring until apparently permanently cured by the radiotherapy.

Adenophlegmons of the Hilum.—Jean has encountered this affection only in about 1 per thousand of his cases of influenza. In one case that came to necropsy the adenophlegmon had dominated the clinical picture and had involved the hilum of the lung where it had induced a large abscess that had opened into a bronchus. The symptoms from the presence of the adenophlegmons tumor are associated with symptoms from the compression of the hilum, but relief follows the irrigation of the pus into the air passages. In

one case the phlegmon emptied into the interlobe. By radiology of every patient with a vomica, it was easy to detect the shadow of the adenophlegmon except when encountered pleurisy of the hilum casts a similar shadow. The pleurisy process soon spreads or subsides, while the adenophlegmon may last for several weeks. In the four cases he has encountered, one of the patients died. He shrank from operating from fear of infecting the mediastinum, and applied only medical treatment as for any cavity in the lung.

Epithelioma of the Glans Penis.—Betancés reports three cases in which a small red bunch had been noticed in the glans penis for about two years and a half, never causing pain or other disturbance, but it kept very slowly increasing in size. Microscopic examination of a scrap from one showed an apparently benign papilloma, but the tissues of the second proved a little more complex, and in the third the microscope showed malpighian basement-celled epithelioma with a pronounced tendency to invade neighboring tissues. The lesion was resected in this case, and a year later pronounced epitheliomatosis of the glands became manifest. The findings therefore testify to the probably malignant nature of these "warts." The three cases represent the different stages: leukoplasia, papillary epithelioma and cancer. The article is illustrated, and Betancés emphasizes the red, uniform velvety aspect of the "warts," scarcely protruding above the level of the skin, but they feel thick when taken between the thumb and finger.

Hot Saline by the Vein in Shock from Hemorrhage.—Dunet conceived the idea that the best way to warm up the patient in shock was to warm him from within by injecting physiologic saline heated to 55 C. (131 F.). This is a temperature just below 56 C. which is the limit of tolerance of thermo-unstable substances. He ventured to apply this as a last resort to a man of 54 who had been bleeding for two hours after the upper third of his thigh had been crushed by a street car. Dunet infused in the femoral vein 2 liters of the heated artificial serum in the course of four or five minutes. Before the close of the injection, the natural tint returned to the skin, the face no longer looked pinched and the pulse could be felt again, the least about 160. At the close of the injection the man spoke, saying he felt warm all over. He was put back to bed and in half an hour said he wanted to smoke.

- *Gastric Cancer with Anasarca. A. Gouget.—p. 329.
*Subumbilical Evisceration. H. Chapt.—p. 331.
*Nature of Wassermann Reaction. A. Verne.—p. 333.

Gastric Cancer with Anasarca.—Gouget has compiled seven cases since Chesnel's five, and reports one personally observed, in which dropsy was an early sign of gastric cancer, the heart and kidneys apparently sound. In some of the cases the anasarca and weakness were extreme but there were no appreciable stomach or kidney symptoms. Necropsy disclosed the cancer in the stomach. In other cases the anasarca seemed to be rather a complication than a clinical form of gastric cancer. In some in this group the whole course was only two and a half months from the first symptoms which were vomiting and abdominal pains. In one case the edema was the first sign of trouble, coming on in the midst of health, with no heart or kidney symptoms. The edema subsided and returned again and again, the man of 59 growing constantly weaker. At the end of three months a tumor was discovered and death occurred two weeks later. The stomach was almost completely filled with vegetations. One woman had no symptoms except the generalized anasarca and weakness till the end came in a few months. In a third group, including his own case, the anasarca kept coming and going for a year or more. The patients came to the hospital again and again during a whole year for treatment of the anasarca, which seemed to be essential dropsy. In one in this group, hematemesis was the first symptom, preceding the anasarca by four days, but there was nothing else for more than six months to attract attention to the stomach. In Gouget's case, the woman of 52 had been healthy until the anasarca and ascites developed. This subsided and recurred repeatedly, one of the free intervals being four months long, under a milk-vegetable diet, digitalis and theobromin. To the very

end there were no gastric symptoms nor even pronounced anemia. The emaciation was masked by the edema. The long and multiple remissions of the edema and the retention of relative good health misled away from the suspicion of cancer, especially as there are no objective manifestations of malignant disease. Nothing is to be learned from examination of the blood and gastric juice; radiology might prove more useful. The chief reliance for differential diagnosis of the cancer is the discovery of occult blood in the stools.

Nature of Seroreaction in Syphilis.—Vernes seeks to demonstrate that the flocculent property of the blood serum is a property that can be measured, and that different classes of serums possess this property in different degrees. Estimation of the degree of turbidity of the serum shows to which class the serum belongs. With a stable colloidal suspension, addition of substances which cause flaking show a whole scale of flocculation reactions according to the substance used. Human serums and hog serum cause different degrees of flocculation in this stable colloidal suspension. It can thus be played on for a whole scale of flocculation reactions, and they can be recorded with precision. He uses for this a colorimetric scale with eight notes like the octave on the piano, with the octaves below and above. The degree of opalescence determines the place in the scale of the fluid being examined. The extent of the flaking with a given fluid is proportional to the amount of the fluid used.

Syphilis augments the flaking properties of normal serum, but this property fluctuates within wide limits although always much above normal in the scale with active syphilis, and the variations are always peculiar to syphilis. His charts demonstrate and illustrate his assertions that infection with syphilis increases the flocculent power of the blood serum. Under treatment with arsenic, this property becomes attenuated and the flocculation may drop to correspond with that of normal serum. If the treatment is inadequate or stopped too soon, the flocculation power becomes more pronounced again. When the flocculation property has kept within normal range for eight consecutive months he has never known further manifestations of the syphilis to develop. In addition to the colorimetric scale he uses a transparency scale to detect the slightest variations in the turbidity. He regards these variations as testifying to the intensity of the infection, and asserts that by this means we have a gauge for estimating the intensity of the syphilitic infection by the variations in the flaking property. The Wassermann reaction sets in play the flaking action of the human serum on the suspension (false antigen) when the flaking power of the serum is sufficient to overcome the resistance to flocculation imposed by a hemolytic dispersion element, such as pig serum. The alleged "antigen" is in reality merely a suspension of a certain physical composition.

Strabismic Amblyopia and Mineral Waters. J. Bouchard, p. 181.

Pathodixia. Lichwitz has coined this term to designate the obsessions and permanent exhibition of an attitude. He does not refer here to the displaying of lesions, but to the attitude, the medical demon of the war. The pathodixia, in its essential phase, is followed by a phase of hyperaesthesia, and this finally settles into an automatic, rigid attitude. It is the exact opposite of the "stagnant" attitude, which Balinski has described under the name of "anostrogia"; the patients apparently unaware of their "compulsion" in their affection, or entirely indifferent. Both of these phases then call for treatment which can be psychodrama.

Gastric Affections and Spa Treatment.—Binet reviews the different indications for different types of mineral springs with stomach affections. He discusses in particular the nervous element in dyspepsia, and the stomach troubles which mask liver disease or gallstone mischief. He asserts that Vichy water, in particular, soothes the spasm of the pylorus and reduces the hypersecretion of gastric juice while regulating liver functioning. With the exception of parasitic dysentery, all intestinal affections seem to improve under a course of treatment with Plombières and Chatel-Guyon waters. Dyspepsia associated with obesity, gout, gravel, oxaluria or diabetes benefits by a course of diuretic waters like those of Evian and Vittel, or a course at Vichy.

- War Psychology. C. Odier.—p. 841. Concluded in No. 24, p. 882.
Influenza. J. L. Burekhardt.—p. 853. Con'n.

War Psychology.—Odier deals here with that branch of war psychology affecting the spine, the imagined inability to stand erect. This has been called *campicoemia* (from the Greek words "I bend" and "the trunk"). The body is bent over in a physiologic attitude, and the neurosis consists in the fact that the subject does not straighten up. His analysis of the neurosis shows that the main factors are a conscious phobia of everything connected with the fighting, and a sub-conscious longing for protection. The whole is thus a phenomenon of autoprotection. The *campicoemia* corrects itself as the man lies flat on his back, and a plaster corset is then applied for two or three weeks, a *période de désincubation forcée*. This method is effectual, but it takes so much time that it has been superseded by what Odier calls *suggestion électro-psychique impérative*, which he describes in minute detail and emphasizes the brilliant successes realized with it in the neuropathic syndromes engendered by the war. The most brilliant successes have been realized with functional paraplegia, but sometimes a sitting of several hours is necessary for this. *Campicoemia* of three years' standing has often been cured by this means in fifteen minutes. He says that it has been styled "brutal," and the men call it "being torpedoed," but we have to fight the blind forces of the sub-conscious, and strong measures may be needed.

Etiology of Influenza.—Burekhardt concludes from this study of the pandemic that some filtrable non-bacterial virus is evidently the primary causal agent. According as other germs intervene on the soil thus prepared, we have the various forms of the disease.

June 14, 1919, 19, No. 24

- Foreign Bodies in the Bladder. R. Hottinger. p. 875.

Foreign Bodies in the Bladder. Among the numerous cases reported by Hottinger was one in which a youth had molded a bogie from beeswax and introduced it into the urethra to prevent bed-wetting, as he was subject to enuresis. The bogie slipped into the bladder and set up obstinate cystitis. Hottinger injected a fluid into the bladder and then injected 12 c.c. of xylol. This floated on the other fluid and dissolved the wax which was likewise floating on the fluid. He had the patient massage the bladder region from time to time, pounding it a little, to facilitate the dissolving of the wax. At the end of the fourth hour a milky urine was voided and as it cooled the wax separated out. The cystoscope showed the bladder free from wax, and the cystitis rapidly subsided. There was only a moderate burning sensation while the xylol was in the bladder, and there had been no further disturbances since. Xylol seems to dissolve wax and paraffin more readily than kerosene, which has been recommended for this purpose.

*Malignant Granuloma. P. Sisto.—p. 209.
*Amebic Liver Abscess. Simoncelli.—p. 222; 24. Pontano.—p. 236.
*Malaria in Italian Troops. C. Pezzi.—p. 239. Confini.
*Differentiation of Pneumococcus from Streptococcus. V. Cavara.—p. 245.

Malignant Granuloma.—Sisto reports a case of typical malignant granuloma or Sternberg's disease in which nothing could be found which suggested a tuberculous origin during life or postmortem or by inoculation of eight guinea-pigs. He cites further Viola's experience that inoculation of some guinea-pigs with glandular tissue from a case of malignant granuloma in which the histologic findings and acid-resisting bacilli suggested tuberculous, resulted in the development of typical Sternberg's granuloma tissue in the guinea-pigs. The surgeon who excised the gland tissue from the patient scratched his finger at the time and he, too, developed enlargement of the glands in the axilla and epirochlear region all of the characteristic granulation type. This mishap was equivalent to a scientific experiment. Even if a tuberculous lesion is found in a case of Sternberg's disease, it may be independent of the latter. Or the Sternberg disease may discover and rouse to activity some old slumbering lesion. Nageli has reported a case in which, by a similar mechanism, in the course of leukemia a tuberculous focus flared up and fatal military tuberculosis ensued. Sisto reproduced in his guinea-pigs inoculated with gland tissue the typical lesions of malignant granuloma, but he did not inoculate other guinea-pigs from them. Others have done this and found that tuberculous lesions developed therefrom.

Treatment of Amebic Liver Abscess.—Simoncelli protests against trusting to medical means for treatment of amebic liver abscess, saying that the possible perforation of the abscess is a constant peril and that no time should be wasted on medical measures alone. He operates at once and supplements this with a course of emetin, and had four recover in his seven operative cases.

Pontano declares that there is no need for such haste. The amebic liver abscess is often months in developing, although instances are known in which the course was only three weeks. Manson has reported cases of a year and more. Hence there need be no hesitation in waiting to give emetin a trial. In a recent compilation of 162 fatal cases, rupture occurred in only thirty-seven of the cases. This includes twelve cases of rupture into the peritoneal cavity; eleven into the pleura; pneumonia in two and peritonitis in only three.

Malaria.—Pezzi analyzes the experiences during 1918 at the Mantegna military hospital at Milan where large numbers of malarial troops were being treated. Intravenous injections of quinin sometimes proved effectual as a last resource but he emphasizes that their sterilizing action is no greater than when the quinin is taken by the mouth. The route by the vein should be reserved for the graver cases and for malignant tertian when first diagnosed. It is in these cases that results are obtained more rapidly than can be realized by the mouth. In pernicious cases with pronounced toxic phenomena the quinin cannot work a miracle, and it may even accelerate the fatal termination by its greater depressing action on the heart when given by the vein. He always gives a subcutaneous injection of caffeine before the intravenous injection of quinin. In three cases there was grave collapse after the intravenous injection, and one patient with exceptionally malignant tertian died. In conclusion he warns that the return of the soldiers to civilian life is all undoubtedly spread malaria, and physicians must be on the alert to detect it, especially the sub-continuous fever from the *Plasmodium praecox*. If this is mistaken for typhoid or tuberculosis, the precious time during which quinin would be really effectual is wasted. He urges to think of malaria first of all and not of typhoid, etc., until malaria can be excluded.

Differentiation of the Pneumococcus.—Cavara utilizes optochin to distinguish between pneumococci and streptococci; this kills the former while it has little action on the

latter. He has been experimenting with different strains of both microbes. When there is no growth of the microbe in bouillon or bouillon serum containing 1:50,000 optochin (with a control test), in one or two days in the incubator, the microbe present is certainly the pneumococcus, but when cultures develop this does not necessarily exclude the pneumococcus as certain atypical avirulent strains seem to be resistant to the optochin. In case of doubt he inoculates the germ in the vitreous body of a rabbit and examines the exudate twenty-four hours later for lancetate forms. His tests showed that typical pneumococci, sensitive to optochin, may become resistant to it when cultivated on artificial media. Streptococci require a concentration of 1:5,000 or 1:3,000 before their growth is checked by it.

Riforma Medica, Naples

May 24, 1919, 35, No. 21

*Calcareous Infiltration. A. Mori.—p. 414.
*Radical Treatment of Bone Fistulas. G. Morone.—p. 416.
*Gonococcus Ophthalmia. V. Diamare.—p. 420.

Calcareous Infiltration.—Mori reports a case of calcareous infiltration of a gouty toe and another of an extensive wound of the thigh from explosion of a gun twenty-four years before. The toe was amputated and a year later the same operation had to be done on the other toe for the same cause. The cicatrix in the other case also had to be resected. In both cases there had been suppuration in the region affected.

Treatment of Fistulas in Bone.—Morone excises the entire tract into sound tissue and opens up the focus with a wide opening, saving as much of the skin as possible. He packs the cavity with gauze and applies a moderately tight bandage. The second or third day he takes out the gauze and inspects to see that not a scrap of diseased tissue is left. Then he draws down and fits the soft parts to the raw surface of the bone and brings the edges of the wound together as much as possible. In tunnel cavities he refrains from draining but keeps the lips of the wound apart with gauze packing renewed every three days. The oozing soon stops and then the lips of the wound are brought together; healing is complete in a month or two except in the largest foci which may take three or four months. He applied this method in fifty cases and had no mishaps.

Gonococcus Ophthalmia.—Diamare calls attention to his experience with 140 cases of gonococcus ophthalmia in which the severest lesions were always those with the gonococcus in pure cultures. When it was associated with the micrococcus, and especially with the Koch-Weeks bacillus, the course was exceptionally mild and the ophthalmia soon healed harmlessly. This suggests the feasibility of using the virus of the Koch-Weeks infection to attenuate the gravity of pure gonococcus ophthalmia. He has had no opportunity since to apply this suggestion in practice as he intended.

Archivos Españoles de Pediatría, Madrid

March, 1919, 2, No. 3

*Malaria in Children. R. Gomez Ferrer.—p. 129.
*Disease of Genital Organs in Little Girls. J. Blanc Fortain.—p. 140.
*Cervical Rib; Two Cases. C. Delport.—p. 154.

Malaria in Children.—Ferrer has found malaria in children of all ages but it is liable to be misinterpreted in infancy, especially as it so often is associated with another infection. In the case of one child of 4, for example, pneumonia kept up a long progressive course with exacerbations as more zones of the lung were invaded. But a tendency to collapse returning at certain hours was explained by the malarial parasite in the blood, and under quinin the clinical picture gradually retrogressed. Any febrile process of an intermittent type in children should suggest possible malaria if it has been in a malarial region or in contact with a person known to have or have had malaria. The mere suspicion does not justify quinin treatment, as various infectious fevers may assume an intermittent type. Inability to discover the plasmodium in the blood does not inevitably exclude malaria, while on the other hand, the discovery of the plasmodium in a healthy subject need not convict him of

malaria. The malaria plasmodium may induce a continuous or remittent fever. When a child seems to have malaria, alone or with some other infection, the laboratory should be consulted but quinin should be given while waiting for the laboratory report or even if the report is negative unless there are formal contraindications against quinin. Physicians who have practiced in a malarial zone are very apt to see malaria everywhere. The glands in the neck may enlarge, simulating glandular fever, but all subside under quinin. One of his child patients was unable to hear quinin, urticaria and distress following its administration, so it had to be abandoned and the malarial attacks recurred for more than two years. Sometimes a change in the quinin salt may prove useful. Subcutaneous injections may prove surprisingly successful. He has never given quinin by the vein but would not hesitate to do so if other measures failed, or in pernicious malaria with a rapid course. If all else fails, change of climate may save the child, especially a change to 3000 feet above the sea or more, but it is wise to keep up the quinin.

*Influence of Sexual Functions in Women on the Defense against Tuberculosis. L. Lasbennes.—p. 125.

*Constitutional Tendencies in Relation to Stomach Disease. R. Saenz de Santa María y Marroñ.—p. 126.

Traumatic Shock.—Diaz concludes his long study of modern conceptions of shock by emphasizing the necessity for measures to raise the blood pressure and combat acidosis. For the former, the most practical method seems to be transfusion of citrated blood, with possibly injection of camphorated oil by the vein, as Heitz-Boyer recommends. It seems to be harmless provided the dose is small and injected very slowly. The acidosis is combated best by sodium bicarbonate by the vein or by proctocolysis.

The Sexual Functions in Women in Relation to Defense Against Tuberculosis.—Lasbennes tabulates the statistics of the tuberculosis mortality at Madrid since 1900, classifying it by sex and age. His figures show a striking reduction in the tuberculosis death rate in women during the child-bearing age and later, in comparison to the male death rate. Up to the age of 20 the female death rate keeps about the same as the male or surpasses it. From 10 to 19 the proportional percentage was males, 41.26, 40.91, 38.22, 47.42 and 41.24, while in females the corresponding figures were 58.74, 59.09, 61.78, 52.58 and 58.76. After 20 the female death rate ranged from 29.59 to 49.46 as the extreme figures, while the male death rate ranged from 50.54 to 70.41, and averaged over 60. His experiences elsewhere confirm this relative lesser reactivity of women and the greater reactivity of girls after puberty, the practical deduction would be to prescribe matrimony in certain cases of "pre-tuberculosis" instead of forbidding marriage in such conditions, as is often done. There is a possibility also that ovarian treatment might prove an effective adjuvant in treatment of tuberculosis.

The Constitution in Relation to Stomach Disease. Santa María relates that over 70 per cent. of his patients with chronic stomach affections show signs of deficient suprarenal, thyroid or genital functioning, manifested especially in asthenia. More than 30 per cent. of all these chronic stomach cases show vagotony and this is responsible for the excessive secretion and peristalsis in the stomach. Even large doses of epinephrin fail to induce the usual reaction, while atropin only briefly modifies the bradycardia which is constant with almost all gastropathies. Suprarenal treatment, rather than treatment addressed to the stomach, is called for in these cases with hypersecretion and vagoneurosis, especially when violent contractions follow the evacuation of the stomach and eating food relieves the pain. The kind and intensity of the stomach symptoms do not determine the prognosis so much as these constitutional factors. He urges medical school inspectors to be on the alert to detect these constitutional defects so that treatment in time may transform these incipient valedictorians. This group now forms almost the entire body of his patients with chronic stomach and liver disease.

*Vertebral Presentation. E. Macías de Torres.—p. 103.

*Sarcomas, Especially in Long Bones. R. Lozano.—p. 109.

Cerebellopontine False Tumor.—In the case reported by Albo and Hormaeche they located the morbid process exactly in the cerebellopontine region, but instead of the anticipated tumor it proved to be a cyst from chronic circumscribed serous arachnoiditis, in the lateral cisterna. There seem to be no means for distinguishing between a cyst and a tumor in this region, and it is a difficult matter to locate the process at an early stage, before important nerves are suffering from the pressure. The necropsy findings in this case suggest that if the extremely tardy and slight participation of the involvement of the right acoustic nerve had been heeded during life, it might have revealed that the process compressing the trigeminal nerve (neuralgia), the facial nerve (paresis), and the vestibular nerve (vertigo and reduced excitability) could not have originated in the acoustic-vestibular trunk nerve. The three cerebellar seizures which the woman had had were at first ascribed to hysteria. These cerebellar seizures or vagal attacks seem to be peculiarly characteristic of tumors in the arachnoid cisternae. Cushing ascribes them to fluctuations in the tension of the fluid in the cisternae. The fact that the first symptoms coincided with some infectious process, puerperal fever in this case, is presumptive evidence in favor of a cystic tumor rather than a solid tumor. The cerebellar hemisindrome may be lacking entirely in cases of arachnoid cyst of the lateral recessus but, on the other hand, the intracranial tension and the atrophy of the optic nerve may be as extreme as with an intracranial tumor. With suppurating otitis or mastoiditis, pus may accumulate in the cerebellopontine region and induce all the symptoms of an intracranial tumor at this point, as the deafness from the primary process aids in misleading the diagnostician. There may even be homolateral cerebellar symptoms. Hormaeche diagnosed and successfully removed an accumulation of pus in a case of this kind.

Endocrine Types in Art.—Rodriguez Mata gives nine reproductions of famous paintings depicting dwarfs, cretins, the obese, and instances of excessive or deficient thyroid functioning. In addition to these, three full-page colored reproductions are given of Ghiberti's Paolo and Francesca, da Vinci's La Gioconda, and Velazquez' Don Antonio. As the page of the *Plus-Ultra* measures 11 by 14½ inches, this issue is an imposing art number. Mata remarks that medical journals might well study the works of the masters as although they may misinterpret some of the special scientific features of the case, yet they record psychic elements which may give the clue to the whole. He regards La Gioconda as an example of slight hypothyroidism, from the eyebrows and the doughy aspect of the face. The reproduction is from the earlier painting at Madrid, not the Louvre copy. Mata does not know of any painting depicting subjects with exophthalmic goiter, but in some which he reproduces, extreme terror or rage is represented by protrusion of the eyeballs, as in Rubens' Battle between the Centaurs and the Lapithae.

Diathesis and Anaphylaxis.—De los Terreros has long been preaching that the diathesis and its manifestations are nothing more than variants of anaphylaxis. The diatheses are more pronounced in children as their biology is unmixed with the panvaccination to which it is subjected later, while their intestinal walls are more permeable to heterologous albumins and their digestive juices are less potent than in adults. In treatment of the diatheses, we should be guided by what has been learned from anaphylaxis in animals.

Lethargic Encephalitis.—Juarros reports the first two cases of lethargic encephalitis to be published in Spain. One was

of such a fulminating type that it proved fatal in less than twenty-four hours from the first signs of delirium, followed by bilateral ptosis and coma, but there had been slight fever and symptoms of catarrhal gastro-intestinal disturbance for four days. The other patient was a young woman; the disease began with a slight chill and mild fever, improving in three days, but the fourth day somnolency developed, with slow pulse, dilatation of the pupil, no pupil reaction to light or accommodation, and abolition of other reflexes, fibrillary tremor of lips and tongue but no Kernig sign. By the seventh day the temperature was high, with trismus and absolute coma. The ninth day the temperature had reached 42.5 C. (108.5 F.) just before death. There were no convulsions at any time, no anuria, the blood pressure was not high and there was no history of kidney disease. Jauros describes these cases as probably lethargic encephalitis.

Page's Osteitis Deformans.—Hauduroy gives the roentgen findings in a severe case of deforming osteitis of the legs, but adds that the cause of this disease is as much of a mystery now as when Paget described the first case, in 1876. His patient is a man of 64 with nothing to suggest acquired syphilis, but certain features of the case history point to inherited syphilis.

Mechanism of Vertex Presentation.—De Torres describes with five diagrams what he calls his new ideas in regard to the mechanism of flexion and engagement of the head with vertex presentation.

Sarcomas.—Lozano refers in particular to sarcomas in the long bones, citing experiences which seem to demonstrate that myelogenous sarcomas are less malignant than those that start in the periosteum. There is less danger of metastasis, and the malignant disease remains long confined to the bone, without contact with soft parts. Hence, after its excision, the question of a bone implant may be considered. This is scarcely worth while with the sarcomas that have invaded the soft parts as, although the patient may stand the operation, yet he has to pass the perils of metastasis.

*Tardy Inherited Syphilis. R. E. Parody.—p. 325.

*Papulous Eruption of Probably Tuberculous Origin. P. M. Barlati.—p. 326.

The Phases of Tuberculosis in Children.—Garrahan discusses the anatomy of the primary focus in the lung with tuberculosis in a child, tabulating and illustrating the principal features in six infants less than a year old and in four children from 2½ to 9 years old. In most of the children there had been nothing to suggest a pulmonary lesion, one child dying of tuberculous meningitis, and three of intercurrent disease, but in all the pulmonary lesion was pronounced, and with it the satellite tracheobronchial adenopathy. His experience confirms the great prevalence of the primary focus in the lung. Acaña found only 3 among 96 tuberculous infant cadavers in which the mesenteric glands were the only ones affected. Ulcerative lesions in the intestines were invariably secondary. The inoculation chancre in the lung and its satellite adenopathy form the initial phase of tuberculosis but it may escape detection. The adenopathy may become more evident while the pulmonary focus remains stationary; this seems to be a special feature of tuberculosis in very young children. Reinfection does not induce these pronounced glandular processes.

The second phase of tuberculosis comprises the diffusion of the process. This may occur by aspiration, by the lymphatics, or by the blood. One infant only a month and a half old had the small cheesy nodule in the lung with its satellite adenopathy and milary generalization, just like experimental tuberculosis in a guinea-pig. With the same findings in a child of 2 there was, in addition, the meningeal lesion which dominated the clinical picture. The older the infant and child when the primary focus develops, the greater the chances for its conquering the infection, that is, not letting it get beyond the first phase. This latent process then is revealed only by tuberculin tests or necropsy. The third phase is the tardy form, reinfections or exacerbations, in

older children and adults. We have then the common chronic pulmonary tuberculosis, generally apical, or tuberculous lesions in bones, liver, pericardium, larynx or pleura, or lupus or certain cases of iritis.

Tardy Inherited Syphilis.—Parody reports the case of a boy of 9 who has had severe attacks of spasm of the glottis since he was 2 years old and lately has been having a dry spasmodic cough, asthma, manifestations of hemophilia and intense anaphylaxis after injection of horse serum to combat the hemophilia. Finally symptoms of meningitis developed. Mercurial treatment was then begun on account of the stigmata of inherited syphilis, and at once the meningeal symptoms, asthma, etc., subsided and the child was in excellent health for several months when he grew nervous again and the spasmodic cough returned. Mercurial treatment was resumed anew and clinically normal conditions were promptly restored and have persisted during the months since to date. The discovery that the inherited syphilis was probably responsible for the whole train of symptoms presented by this child suggested mercurial treatment at once when another child in the same family began to develop asthma and asthmatic bronchitis in the same way. No benefit was derived from ordinary treatment but under mercury the improvement was as surprising as in his brother's case.

DÉBRIDEMENT *

DEAN D. LEWIS, M.D.
CHICAGO

Débridement, as employed surgically, has been defined as an incision of a wound made with the view of facilitating the discharge of pus. It might be more properly defined as the excision of the devitalized tissues or debris resulting from the action of any traumatizing force, with the view of preventing the development of infection.

Excision of devitalized tissue has always been practiced to some extent in traumatic surgery. It was, however, not practiced to any great extent at the beginning of the war because of the teachings of military surgeons which were based on the experiences gained in previous wars. As the result of observations made in these wars, gunshot wounds when first received were treated conservatively and active surgical interference was postponed until infection had developed.

Two factors in the recent war made necessary the return to débridement which was advised and rather extensively employed by Larrey in the Napoleonic wars. These factors were, first, the high explosives, which, when they strike, tear and devitalize large pieces of muscle and shatter bone, and second, highly virulent bacteria which were present in the soil of the country over which the contending armies fought. This soil had been intensively fertilized for years.

The tissues devitalized by the high explosives formed a culture medium for the bacteria introduced with the shell fragment or pieces of clothing. In order to prevent gas gangrene, which might necessitate amputation or cause death, or suppurate, thus prolonging disability and preventing the return of men to the firing line, it became necessary to remove this dead tissue which formed the medium of growth for these organisms and to make a new wound the borders of which were formed by healthy tissues capable of inhibiting the growth of bacteria or preventing their extension when once developed.

PRIMARY INFECTION OF WOUNDS

The amount of infection carried into a wound usually depends on the shape and character of the missile, whether it is smooth or irregular, with sharp, jagged edges. A machine-gun or rifle bullet may perforate the soft parts, causing a long wound track but carrying

in no infection at all or so little that the tissues which are usually only slightly damaged by a missile of this character can take care of the bacteria which are introduced. A smooth shrapnel ball, of which relatively few were seen during the latter months of the war, may be cleaned in its passage through the superficial tissues, so that infection, if it develops, may remain superficial, while the deeper parts of the wound may remain sterile and manifest no inflammatory reaction.

The irregular pieces of high explosive, on the other hand, carry infection deep into a wound, and frequently, when they pass through clothing, carry a small piece of cloth containing virulent bacteria ahead of them. Fragments of high explosive have also a more destructive action on tissues than do either undistorted machine-gun or rifle bullets, and destroy large pieces of muscle which form a medium in which the bacteria carried in by the shell fragment or clothing rapidly develop.

PERFORATING WOUNDS OF SOFT PARTS

Perforating wounds of soft parts caused by undistorted machine-gun and rifle bullets or shrapnel should be treated conservatively. It is not necessary, in most of these cases, to even debride the skin surrounding the wound of entrance and exit. Some superficial, gutter wounds, caused by the missiles just mentioned, may be painted with iodine and dressed with dry gauze. In the majority of cases, however, gutter wounds should be excised, for excision is easily performed without any disabling consequences, and healing takes place much more rapidly.

Shell fragments, irregular, distorted, machine-gun or rifle bullets and shrapnel balls, if superficial, should be removed as early as possible. Some question often arises as to the advisability of removing bullets which are not misshapen, shrapnel balls and minute shell fragments. It should always be considered whether the damages done the tissues in the attempted removal do not outweigh the advantages of removal. A foreign body in the belly of an important muscle will usually have to be removed. A foreign body resting close to the wall of a large vessel should be removed for it may later cause pressure on the vessel wall, resulting in hemorrhage and subsequent aneurysm formation. The more irregular a foreign body, the sooner it will cause trouble and the greater it will be.

FUNCTION OF THE TRIAGE OFFICER

The triage officer has an important function to perform. He can sort those cases on which iodine and a dry dressing can be applied from those which require operation consisting of removal of the foreign body. The gravity of the lesion is not indicated by the size

* Read before the Section on Surgery, General and Abdominal, at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

* Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints.

of the wound. A bullet may cause a perforating or a penetrating wound, the wounds being relatively large, but they will often heal without complications, whereas a small fragment of high explosive may make a small wound in the skin while the underlying tissues may be badly damaged or devitalized.

As a rule, I believe it may be said that all wounds caused by high explosive, except some gutter wounds in which the foreign body has very evidently not entered the deeper tissues, should have a roentgen-ray examination and be seen by a surgeon.

The greater number of the wounded which pass from the receiving tent to the dressing tent will be made up of those who have sustained bullet wounds involving the soft parts or superficial wounds caused by other forms of missiles which have not entered muscle tissue.

GUTTER WOUNDS

Gutter wounds caused by bullets or fragments of high explosive should be excised whenever muscle has been exposed and injured. These wounds are sometimes neglected because superficial. Gas gangrene may, however, develop in such wounds, and when this type of wound is not inspected or is neglected because apparently so insignificant, the gas gangrene may extend considerably before being discovered. Such wounds may be easily excised, and the results following excision are usually not disabling because the wound is superficial.

LOCAL ANESTHESIA IN WAR WOUNDS

It has been advised that local anesthesia be used in the excision of the smaller wounds of this type. I do not believe that local anesthesia should be used in the excision of war wounds. The excision is frequently not well done under local anesthesia, for a wide enough dissection is not made. Infiltration anesthesia may also force bacteria into deeper tissues. If a deep anesthesia is not desired in the excision of such wounds, the operation may be performed in the early stages of general anesthesia.

These gutter wounds are excised by elliptical excisions which should be made at least one quarter of an inch from the margins of the wound. The distance at which the incision should be made from the margins will naturally depend on the pathologic changes in the muscle. Muscle which is infiltrated with blood should be excised, as also should the hyaline noncontractile muscle, which is found when gas gangrene has developed. In the débridement of muscle, the excision of tissue should be carried back to muscle which contracts readily and bleeds. After one edge of the gutter wound has been freed, the incision may be made on the other side.

Care should be taken that the tissues incised are not infected from the surface of the wound, and that during excision the incision is not carried into infected tissues. In other words the excision should be en bloc. If the wounded can be kept for any length of time so that they may be observed for a few days, primary suture of wounds of this type may be attempted. In

evacuation hospitals, during active work, primary suture of wounds of this character should not be attempted because of the rapid evacuation of wounded which does not permit of observation.

As previously stated, perforating bullet wounds should be treated conservatively unless there are distinct indications for surgical intervention. When there is an explosive wound of exit the tissues about it should be excised. Excision is easily performed in cases of this type for the badly injured tissues are superficial or have been exteriorized. The deep parts of such a wound may be regarded as sterile and excision should be confined to those tissues which have suffered from the explosive action of the missile.

PENETRATING BULLETS

Penetrating bullets should be removed. Bullets are usually easily removed after definite roentgen-ray localization. If removed, they will cause no trouble later. When removed after roentgen-ray localization, the incision, usually a short one, is made over the bullet and no attention is paid to the track of the missile. In some cases, however, a bullet may cause considerable damage. This happens frequently when the muscles are on a stretch when struck.

Vascular injuries, accompanied by hemorrhage and nerve injuries, may complicate either penetrating or perforating bullet wounds. One of the most typical examples of vascular injury with hemorrhage is seen in the transverse perforating wounds of the calf, in which the posterior tibial artery is injured. The leg has a tense feeling and is swollen. In cases of hemorrhage occurring in wounds of this type, the injured vessels must be ligated after the clots are removed, but as a rule no tissue will have to be excised. When there are evidences of nerve injury, the nerve in the track of the bullet should be explored. If the nerve has been divided, a nerve suture should be performed. The injured tissue of the nerve should be excised until neurofibrillae herniate from the cut end of the nerve. If suture is attempted without resection of the softened, fused nerve ends infiltrated with blood, the results will be bad because of the scar tissue which forms at the line of suture.

Fig. 1.—Result following débridement of high explosive wounds of the limb. Removal of fragments of high explosive, also of the devitalized portion of the gluteus maximus muscle, was performed.

TREATMENT OF WOUNDS CAUSED BY SHELL FRAGMENTS

Wounds caused by fragments of high explosive, as previously stated, demand much more careful consideration than do those caused by bullets. No wound caused by high explosive should pass through the hospital without a roentgen-ray examination and careful examination by a surgeon, unless the amount of work is so great that the wounded will receive attention earlier at some hospital in the rear. It becomes necessary at times to send the wounded back to centers further removed from the front than the evacuation hospital, but when such trains are sent back there should be some assurance that the wounded will receive treatment sooner than they would at the evacuation hospital to which they are first sent, which may for a time be

unable to handle the work on account of the number of wounded that have been brought back.

PERFORATING SHELL WOUNDS

Perforating wounds may be superficial or deep. The superficial wounds often form a short tunnel, while, in other cases, the explosive force of the missile lays open the skin or lacerates the underlying muscle which is infiltrated with blood and devitalized for some distance. There is likely to be more laceration of tissue and destruction of muscle in wounds of this character than in the gutter wounds that have been described. In these perforating wounds, removal of the foreign body does not have to be considered.

In the superficial perforating wounds, the track may be excised en bloc without contamination of the surrounding tissues by passing a piece of gauze which is used as a guide through the wound. The excision is made far enough away from the tissues that have been devitalized, the gauze being used as a guide, to avoid the soiling of surrounding tissues.

The passing of gauze through a perforating wound of any kind and then making sawing motions with the gauze so inserted is bad surgical practice and should never be employed. Gauze used in this way may remove gross dirt and blood clots from a wound track, but the muscle coming in contact with the gauze is contused and any bacteria on the surface are rubbed into the deeper tissues.

It has been suggested in perforating wounds of relatively deep levels, when it is thought that the circulation of the tissues about the track is good, that the tunnel may be cleaned by passing forceps along it, and then drawing through it a suitably thick strip of gauze, which will remove the larger foreign particles and blood clot. Successive strips of gauze should then be drawn through, the sawing motion always being avoided. Finally, a strip of gauze considerably narrower than the diameter of the tunnel, and impregnated with antiseptic paraffin or petrolatum, should be pulled through and left in situ. This method of treatment of some tunnel wounds has been

suggested by one of the chief advocates of the excision of war wounds. I believe it to be a dangerous procedure. Perforating wounds of the type just described, whether superficial or deep, should always be thoroughly excised or debrided. The tissue should be excised en bloc when possible. The excision will often, of necessity, be done piecemeal but should be carried into healthy tissues. Disastrous results may follow even the method of treatment just mentioned. The safest procedure should, however, be followed, although it must be confessed that gas gangrene has occasionally followed débridement. When it has followed, it has been owing to error in judgment as to the pathologic condition of the remaining muscle and not to the employment of a faulty surgical procedure or at least one of doubtful value.

PENETRATING SHELL WOUNDS

In this type of wounds, the foreign body must be removed. As there is no wound of exit, it may be more difficult to follow the track of the wound. Accurate roentgen-ray localization of the foreign body is necessary in all these cases for it may not be possible to follow along the track and reach the foreign body, and a counter-opening may have to be made over it in order to remove it. The distal end of the wound track may be found after the foreign body has been located, and the entire wound track may then be excised or debrided.

It is often difficult to follow the deeper parts of a wound track after the superficial portion has been excised. If the injured extremity is moved slowly, so that the deeper planes of muscles are made to assume different relative positions, the deeper parts of the track may be seen. In the relatively superficial wounds, it may be possible to insert the finger into the wound track and feel the foreign body. A probe or grooved dissector may be passed along the finger until it meets the shell fragment and may then be left in position to serve as a guide.

Special attention should be paid to the bed of the foreign body, which not infrequently carries in pieces of clothing. Cases were repeatedly seen in base hospitals in which the wound of the soft tissues which had been excised had almost entirely healed, only a small sinus remaining. Pieces of clothing were not uncommonly found in such cases. The foreign body had been removed, rather blindly perhaps, but the pieces of clothing had been allowed to remain.

In cases in which multiple shell fragments have lodged close together, the muscle will be badly damaged. I have seen cases in which several small fragments of a shell have lodged close together in the gluteal and in the hamstring muscles. Multiple small fragments when lodged close together destroy the muscle. They frequently have what may be described as a grinding or churning effect. Such wounds are very susceptible to gas gangrene.

These foreign bodies cannot be removed singly, and it would be poor surgery to attempt removal in this way if possible. The devitalized muscle in such instances should be excised en masse, the foreign bodies being removed with the muscle. In wounds of the character just described, all the hamstring muscles from their points of origin to their points of insertion may have to be removed. In injuries of the gluteal region it may be necessary to remove the greater part of the gluteal muscles. This surgery, seemingly very radical, is, however, conservative, for wounds such as those just described are especially susceptible to infections by gas-producing organisms.

METHOD OF PERFORMING DÉBRIDEMENT

It is difficult to give any definite instruction regarding débridement for the reason that types of wounds

Fig. 2.—Scar following extensive débridement of muscles on outer surface of thigh.

vary so much. There is as decided individuality exhibited in this kind of surgery as in that of civil practice. There are, however, certain general principles which should be followed.

Skin and subcutaneous tissues should, as a rule, not be widely debrided, for they are not usually involved in the types of infection which occur in war wounds. The resulting wounds when they can be well covered by skin are much less disabling when healing occurs. The skin in face wounds should be debrided little, for facial wounds heal rapidly. The badly soiled tissue should be removed, but no wide débridement should be attempted. All tissue, especially skin and subcutaneous tissues, should be saved in war wounds of the face when possible.

In performing débridement, an anatomic dissection should be made. The skin and subcutaneous tissues should be incised over the wound track and the tissues exposed by sharp dissection, down to tissue which is evidently devitalized. Devitalization is indicated by hemorrhagic infiltration of the muscle, and by failure to contract and bleed when pinched with tissue forceps or cut. Muscle, the seat of gas gangrene, has a peculiar waxy appearance and is rigid. It looks somewhat like muscle which has been boiled a short while. Muscle which is the seat of such changes should be entirely removed.

Considerable criticism has been raised against the transverse division of muscles during débridement. Undoubtedly, muscles have been divided transversely, but the foreign body has in many instances already caused the division. It is better to divide a muscle transversely, provided this does not interfere with its blood supply, than to leave a poorly debrided wound.

SMALL FOREIGN BODIES

Small foreign bodies are sometimes found with difficulty. The question arises in these cases as to how earnest an attempt should be made to remove the foreign body. An extended search should not be made for small foreign bodies because of the added injury to the muscles about the wound track which increases the dangers of infection. The track leading down to such a foreign body should be incised and provision made for drainage. Any foreign body which is left without provision for drainage is, however, a source of danger. I have seen a late infection that clinically resembled malignant edema develop about a small foreign body which had lodged in the muscle of the thigh, and had been overlooked in the roentgen ray examination. This late infection developed four weeks after the wound was received.

Small foreign bodies in the hands and face should be left unless superficial and easily removed. They pass through no clothing when entering these parts. The danger of infection therefore is not so great, and attempts at removal would leave disabling or disfiguring scars.

Wounds of the muscles at the base of the neck, of the circumscapular group, of the buttocks, of the thigh and calf should always receive special attention. These are large muscle groups which are often ground or

churned by fragments of high explosive. In cases in which there are multiple wounds, and the condition of the patient is such that all cannot be debrided thoroughly, the groups just mentioned should be operated on and the work done thoroughly because they are so prone to gas gangrene.

The operation of débridement has gained a bad reputation because of some of the extensive operations that have been performed, but in some of these injuries it is necessary to remove the greater part of the gluteal muscles or all of the hamstring muscles because they are destroyed. Radical débridement in such cases hastens convalescence, for these muscles would slough away if allowed to remain, as infection would certainly occur. A radical operation is the surest preventive of gas gangrene.

The blood supply of muscles should be carefully studied. A portion of a muscle deprived of its blood supply should not be left. The most typical examples are the rectus femoris and the superficial muscles of the calf. If the rectus femoris has been divided transversely, the distal part, deprived of its blood supply, should be removed.

In transverse perforating wounds of the calf associated with division of the posterior tibial artery, I believe that it is good practice to remove all of the superficial group of muscles, because the blood supply to these muscles is either destroyed by the foreign body or interfered with when a conical débridement is done.

Removal of the entire group reduces the muscle mass which requires a collateral circulation, and prevents the development of gas gangrene in the part of the muscle distal to its blood supply.

After débridement, a dressing should be applied over the surface of the wound. Gauze should

never be packed into a wound but merely laid on the surface. Dry gauze or moist gauze, which soon becomes dry, is removed with difficulty from these wounds. Removal usually causes severe pain and injures the granulating surface. Petrolatum gauze or gauze impregnated with anti-septic paraffin is the best for this purpose.

When débridement of soft tissues is attempted, it should be radical, but performed with a thorough knowledge of anatomy. A clean dissection with a sharp knife should be made, the tissues should be handled gently, and the tissues adjacent to the wound should be protected from infection. The principles of surgery observed in civil life should be conscientiously followed in débridement.

REMOVAL OF BONE FRAGMENTS

Opinions differ as to the extent to which bone fragments should be removed in cases of compound, comminuted fractures caused by missiles. The line of treatment to be pursued depends again on the character of the missile. Many fractures of the long bones caused by bullets will heal if iodol is painted over the wounds of exit and entrance, and a dry dressing is applied. This statement applies to perforating wounds in which the wounds of exit and entrance are small.

Fig. 3.—Débridement of wound on inner surface of arm and forearm. The paralysis of the ulnar nerve should be noted. Primary nerve suture was not attempted.

In cases in which fragments of bone have been driven through the skin and a large wound of exit has been produced by a distorted missile or bone fragment, the soft tissues must be excised and the detached particles of bone removed. From experience gained after the observation of fractures in evacuation, base and general hospitals, it seems to me that fragments of high explosive have a much more destructive action on bone than bullets. The action of the traumatizing force probably does not differ, however, but a high explosive wound is more frequently infected. The more extensive and more common necrosis of bone fragments after high explosive wounds is probably due to the infection which practically always follows rather than to any differences in the traumatizing force. Bullets should be removed if they lodge in the part involved after fracture of the bone. Bullets which lodge in the tissues and do not perforate are usually traveling at a low velocity and are much more apt to carry in infection than perforating bullets traveling at high velocity.

The question as to whether amputation should be performed or not is easily determined in most cases. Injury of the principal artery of the extremity or nerve injuries with loss of great lengths of the main nerve or even localized gangrene in the distal part of the extremity, after ligation of either the main artery or vein, are indications for amputation.

As to the extent to which bone fragments should be removed, opinions differ considerably. Colonel Burghard states in his preface to the English translation of the "Traitément des Fractures" by Prof. R. Leriche:

Put concisely, the position is, that one school regards as its bugbear possible want of union as the result of removal of fragments from an infected fracture, while the other attaches prime importance to the persistent suppuration and loss of function to which the retention of septic fragments is likely to lead.

From the cases of osteomyelitis that I have observed in U. S. General Hospital No. 28, of which we have over 400, I am convinced that an insufficient débridement results in long convalescence and considerable disability due to sclerosis of the muscles adjacent to the suppurative osteomyelitis. It is difficult in compound fractures of this type to determine how much to excise.

There should be no hesitation about removing fragments that are driven into the medullary cavity, for these must be removed in order to secure drainage of the marrow cavity, nor those which have been driven into the soft tissues, for these will no longer take any part in the regeneration of bone. In some cases which I have seen there have been a large number of sequestrums. Phemister recently removed twenty-three small sequestrums from an infected high-explosive fracture of the left humerus. There is no chemical method of sterilizing these fragments, and osteomyelitis, accompanied by infiltration of surrounding muscles and the

danger of repeated pathologic fracture, cannot be obviated unless these fragments are removed.

It seems to me, in the light of experiences that I have recently had, that fractures were not sufficiently débrided. In many cases it would have been better to have performed some modified type of subperiosteal resection at the site of the fracture, removing in this way all completely detached fragments, and even in some cases those fragments concerning which there was some uncertainty as to whether they were attached or not. This statement applies especially to fractures of the femur, for the femur has apparently greater callus-producing power than either the tibia or humerus.

Hurley and Weedon state that nonunion in cases of compound fracture of the femur in men of military age is extremely rare, being not more than 1 per cent., and that even when the fractured ends of the femur have been separated as much as 3 inches, firm union has resulted.

Removal of the foreign body may be difficult in many of these cases because in palpating the tissues it may be practically impossible to differentiate the foreign body from the bone fragments. In fractures of the thigh, it is often advisable to incise longitudinally the fascia lata in order to relieve tension. This practice may be employed to advantage in other parts where there is a strong surrounding fascia.

TROUBLESOME INFECTED FRACTURES

A type of infected fracture which has caused trouble is the one with tunnels and large cavities. Many of these are caused by perforating foreign bodies, while in others the mechanism of production is difficult to determine. This type of fracture, when infected, continues to discharge until one of the walls has been removed, and the soft tissues are allowed to come in contact with the tunnel or cavity.

In débriding fractures, it would in most instances be impossible to determine whether or not a tunnel or cavity would form. If there were apparently the chance of such a formation, it would be advisable to remove the wall which was most detached or apparently most devitalized. This procedure would shorten convalescence and lessen the disability associated with this type of infected compound fracture, which is often long.

In fractures involving joints, considerable judgment must be exercised in determining the type of operation to be performed. Gunshot fractures of the upper end of the humerus and about the elbow often demand excision. In fractures of this type involving the head of the humerus typical excision of the head of the humerus should be performed. In fractures involving the elbow joint, atypical excision should be performed. Soiled muscle and synovial membrane and detached bone should be removed.

In T fractures of the lower end of the femur, it may be difficult to decide on the type of operation. T frac-

FIG. 4. Result after débridement of extensive wound of right thigh. There is paresis of extensor muscles due to injury of anterior crural nerve.

tures in which metallic fragments have been scattered along the vertical part of the T may require amputation. In cases in which a condyle is detached, it is a question whether resection followed by a stiff knee would not be preferable to a knee in which a part or all of one condyle had been removed resulting in a more or less flail joint.

Badly comminuted fractures of the patella are not uncommon in war surgery. Entire removal of a badly comminuted patella becomes a necessity. This subject must be considered in its relation to wounds of the knee-joint. Excision of such a patella should be carefully performed, and great pains should be taken to avoid injury of the knee-joint. In some cases, where there is difficulty in repairing the defect after removal of the patella, the ligamentum patellae may be split longitudinally and each half sutured to the corresponding expansion of the quadriceps femoris tendon in which the patella was embedded. When the patella is removed, there is usually a small area directly in front of the knee-joint that cannot be covered by the capsule of the joint. An attempt should always be made to cover this defect with surrounding tissue, and usually it can be done. Mobilizing the suprapatellar bursa and displacing it downward is a good method of accomplishing this.

WOUNDS OF JOINTS

The results following wounds of joints were bad during the earlier periods of the war. It has been stated that at a joint meeting of French and British surgeons, held near the end of the first six months of the war, it was painful to hear from representatives of both nationalities the reiteration of the deplorable results in these cases: amputation—death. Over the record of a healed stiff joint one felt almost inclined to cheer, while a story of movement following operation sounded like a fairy tale.

The results were particularly bad after penetrating wounds of the knee-joint. Later it was demonstrated that the principle of debridement could be applied successfully to joints. In attempting to attain the ideal—removal of the foreign body and excision of the wound track, followed by closure of the joint cavity with preservation of joint function, imperfect results may often follow. If infection occurs after such an operation nothing has been lost.

Wounds of the knee-joint are more common than those of any other joints, and the results are, as a rule, more disastrous when infection occurs.

The principles to be outlined in the treatment of wounds of the knee-joint may be applied to wounds of any other joint and therefore only wounds of the knee-joint will be considered. The principles to be

followed depend on whether the wound has been caused by a bullet or by a fragment of high explosive, and on whether the foreign body passed through the joint or lodged within it. The procedure to be followed will depend also on the amount of damage to the bones entering into the formation of the joint.

A bullet may pass superficial to the synovial membrane but may contuse it enough to cause hemorrhage into the joint. Perforating wounds which pass through the synovial membrane may produce a similar picture. In wounds of this type, as well as in wounds caused by bullets which perforate the bone, conservative treatment should be followed. Iodin should be applied to the wounds of entrance and exit and a dry dressing applied. The joint should be aspirated, for the removal of blood is indicated to lessen pain. The reduction of tension will also lessen the chances of infection. When the bullet lodges between the articu-

lar surface or penetrates the bone after passing through the joint cavity, it should be removed.

Wounds caused by high explosive must be treated early and the treatment should be radical. Accurate roentgen-ray localization is absolutely essential to success. Three, four or more pieces of high explosive may enter the joint. Pieces of clothing are usually carried in by the fragments. Not infrequently these pieces enter the joint cavity without injuring the articular cartilage or bone. Just as careful technic should be employed in these cases as in operations performed on the knee-joint in civil life. The tissues should be carefully protected and the wound track removed en masse. If the foreign body is in the tissues it should be removed with the tissues. Gutter wounds of the condyles of the femur should be chiseled away, so that, when the operation is completed, no wound track which has been infected by foreign bodies remains. A bloodless field, ob-

Fig. 13. Gunshot wound of the elbow, necessitating resection of the upper end of the radius and the ulna. The motions of the joint are good. The function of the joint is so good that the patient is able to do considerable work.

tained by constriction, facilitates this operation, as Speed has shown, and may render differentiation of the wound tract clearer. Instruments coming in contact with soiled tissue should be put aside. Gloves and linen about the field of operation should be changed when necessary.

After the operation has been completed, ether may be poured into the joint before closure. I am not convinced, however, that ether has any influence in the prevention of infection in these cases. Closure of synovial membrane and superficial tissues is the next step in the operation. Such wounds, unless there is very evident infection, without much possibility of control, should always be closed. The capsule should be closed and the skin wound left open in those cases in which the tissues have been much soiled. If the

débridement has been thoroughly done and the subcutaneous tissues are not much soiled, the skin, also, may be closed. Interrupted sutures placed at wide enough intervals to permit of the escape of wound secretion should be employed in cases of this kind.

After débridement of a joint, evacuation of the patient should be postponed until one is reasonably certain of the outcome. If infection develops, in transit, the patient cannot receive the care which an infection of a joint demands and by the time the base hospital is reached, where such care can be given, irreparable damage to the joint may occur. A certain number of beds should be reserved in an evacuation hospital for patients with joint wounds, pending decision as to the result of the operation.

During transport, fixation of the joint is a *sine qua non* of success even in the simplest cases. This fixation is easily secured by a Thomas splint. No extension is necessary and the adhesive tape is applied merely with the intention of fixing the splint in position.

Experience with a few cases of primary suture indicates the advisability of attempting to suture nerves at the evacuation hospital. We have at the present time nine cases of primary nerve suture at U. S. General Hospital No. 28 at Fort Sheridan. Seven of these patients are well on the way to recovery or have completely recovered motion. Reconstructive surgery, especially of the peripheral nerves, should begin earlier and in more advanced units than has been the case.

While discussing débridement, I would like to emphasize the necessity of removing the nerve tissue which is softened and infiltrated with blood after a nerve is severed by a missile. The several nerves that I operated on in evacuation hospitals appeared as if fused, and in order to secure healthy neurofibrillae, which should always be exposed when a nerve suture is done, it was necessary to resect the softened, devitalized tissue on each side of the point of division.

Primary suture will not always be successful, but there will be enough successes, as shown by the number of recoveries that have already occurred, to justify it. If there is no return of function, nothing has been lost, for the secondary operation can always be done.

In the cases in which I have performed primary nerve suture, it was necessary to resect so much of the nerve ends that it was impossible to make an end-to-end suture, unless the parts were placed in proper position. In cases of suture of the sciatic nerve it has been necessary to flex the knee to 65 or 70 degrees. When the parts have been placed in such a position to permit of end-to-end union, the fixation dressing should not be removed before four weeks and then the normal position should be assumed gradually.

One would suppose that the final results of débridement would be very disabling. I have been surprised to see how little disability results, even after extensive débridement of rather large muscle groups. The most marked disability has resulted from the division of tendons, a practice which should be discouraged, for it is unnecessary. Synergistic groups of muscles are, to a greater or less extent, able to take over the action of muscles which have been partially or almost totally removed, and to perform the function so well that little disability results.

Débridement, employed so extensively in war surgery, is a procedure which could be used to advantage more commonly and more extensively in the traumatic surgery of civil life.

WAR WOUNDS

PRIMARY AND SECONDARY SUTURE*

EUGENE H. POOL, M.D.

NEW YORK

There are two conditions under which war surgery is performed at the front: first, relatively quiet periods; and second, times when military activities are acute. In quiet times, a thin but fairly continuous stream of wounded are passed back to the forward hospitals; but only occasionally, as after a raid, does congestion occur. The wounded usually can be operated on almost as soon as they are received; there need be no hurry, and the patients can be carefully watched after operation. The aggregate of such cases along a wide sector in quiet periods reaches formidable figures.

The ultimate aim of treatment is to restore the soldier to full activity, with complete restoration of function, in as short a time as possible. Obviously, one of the conditions of such restoration is the repair of the wound. During quiet times, early closure of the wound may be undertaken successfully in a large proportion of cases. Great benefit thereby accrues both to the patient and to the service. But the long, relatively tranquil periods also are of use in affording an opportunity for study and demonstration as to what may be done and what should be done under the varying conditions of war surgery. As a result of such study of technical methods and tissue repair, rules may be formulated and safely enforced for the treatment of the wounded during periods of greater activity.

It must be recognized, therefore, that local conditions, such as the degree of battle activity, alter materially the indications for suture, particularly for primary suture, in the advanced area.

With these preliminary remarks I will outline the general principles and technic of the three varieties of suture of war wounds, namely, primary suture, delayed primary suture and secondary suture.

We will consider first, wounds of the soft parts. The immediate aim of treatment is the prevention or limitation of infection. This is accomplished primarily by débridement of the tissues, that is, excision of the tract, removing devitalized and contaminated skin, subcutaneous tissue, aponeurosis and muscle, together with shell fragment (or other projectile), clothing and micro-organisms contained within the tract. However skeptical one may be as to the complete removal of devitalized tissues and pathogenic micro-organisms by this procedure, many of the wounds, after such an operation, undergo repair as if aseptic, and cultures and smears are often sterile.

PRIMARY SUTURE

The débridement¹ having been completed, the choice of treatment lies between primary suture and leaving the wound open. If ideal conditions, that is, early and thorough débridement, have been approximated and the case can be watched for some days, primary suture may be made. Otherwise, the wound is left open and sutured subsequently. Obviously, the deci-

* Read before the Section on Surgery, General and Abdominal, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

¹ Débridement is here used to include incision, excision of devitalized tissues, and removal of foreign body.

sion in a given case, as to whether primary suture may be made, must be attended with much uncertainty; a mistake may be costly to the patient. In active periods, as in an offensive, when there is a large number of wounded, the exigencies of a service demand haste in the primary operation, and the patient must be evacuated, passing from the operator's control soon after the operation. Under these conditions, primary suture should not be considered. It may be employed, therefore, only in quiet periods and in hospitals where patients may be retained for observation.

The advantages of primary suture are obvious; the disadvantages consist chiefly in the danger of closing within a wound, especially within a wound imperfectly debrided, noxious micro-organisms, particularly anaerobes of the types which produce gas gangrene. A resulting gas bacillus infection or a pyogenic infection in a few cases will counterbalance many successful closures. The only means of rendering primary suture safe is by extreme operative care and thoroughness, thoughtfulness and judgment in the selection of cases and, finally, scrupulous watchfulness for some days after the operation.

When the general conditions are such as to warrant primary suture, many considerations must be weighed in each case in deciding whether suture is indicated. These considerations are:

1. The interval between the receipt of wound and the operation, the type of tissue and situation of the wound. Thus, wounds involving the muscles of the calf, thigh or gluteal regions should not be closed as a rule after a longer interval than eight hours. In these muscular parts, gas bacillus infection is prone to occur and to result disastrously. In other muscular parts the time often may be extended to about twelve hours. In wounds not involving muscles the time may be further extended. It must be understood, however, that such rules based on the time between the injury and the operation are not absolute and have been advanced only as a suggestive working basis. Wounds of the face and scalp are regularly sutured. Wounds of the hands should, as a rule, be sutured. Extensive wounds of the feet should, as a rule, be left open, treated by the Carrel method, and closed subsequently.

2. Extensive laceration of the soft parts or the presence of a large shell fragment or considerable clothing in the tissues shortens the time within which primary suture may safely be made.

3. Conditions which demand haste in the operation, and therefore militate against thorough and painstaking débridement, preclude primary suture; for instance, multiple wounds, condition of shock or period of a rush.

4. Diminution of the vitality of the parts, especially as a result of vascular lesions, precludes closure; for instance, wounds of the calf with the posterior tibial artery sectioned, or marked infiltration of the tissues with blood.

5. As has been emphasized, primary suture must not be made unless the patient can be watched carefully for days thereafter. Accordingly, it was a general rule in the American Expeditionary Forces that during active periods no primary suture of wounds of the soft parts should be made except in wounds of the scalp, face, hands, as enumerated above.

Technic of Primary Suture.—Thorough débridement is essential, and aseptic technic must be observed

throughout the operation. Hemostasis must be complete. The wounds should be washed sufficiently to remove blood clots and loose fragments of tissue. Many operators, after drying the wound, apply ether to the wound surfaces; this, however, is empiric. Lemaître applies tincture of iodine to fix residual micro-organisms. It is questionable, however, whether the ether or the iodine are factors of importance. The muscles and aponeurosis are approximated with interrupted catgut. As little and as fine catgut should be introduced as will approximate the tissues and obliterate dead spaces. The skin and subcutaneous tissues are closed with interrupted silkworm gut. A drain is rarely needed, but should be employed if there is likelihood of oozing. It should be removed as soon as possible; in general, within twenty-four hours. Silkworm strands, rubber tissue or split tube should be employed according to the indications. In some cases, especially in deep wounds of muscular parts, a few strands of silkworm are advantageous as a means of obtaining subsequently a culture from the interior of the wound. At the first dressing the silkworm should be removed and cultures taken; and if hemolytic cocci are found the wound should be reopened (Gross). After the dressing has been applied, the part should be immobilized.

Partial primary suture of wounds of the soft parts has nothing to recommend it; it is often harmful; it should, therefore, rarely be employed.

A wound which has been closed by primary suture should be examined within twenty-four hours; moreover, the general condition of the patient should be carefully watched. These precautions cannot be too strongly urged. If they are observed, there is not much danger of fatal infection; if they are neglected, avoidable fatalities will occur. It is, in general, the failure to recognize the development of gas bacillus infection or pyogenic infection as early as one should, and the unwillingness to admit failure of the primary suture with complete reopening of the wound and free excision of gangrenous muscle, that cause the fatalities.

When gas bacillus infection develops after primary suture, its onset is usually suggested by local tenderness or spontaneous pain in the wound after twelve hours, or by changes in the general condition of the patient which should be watched for and immediately recognized. These changes can be noted, as a rule, in about eighteen to twenty-four hours after the operation. They are rapid pulse, peculiar gray appearance of the face, and moderate rise of temperature, for instance, to 101. The condition, if left, rapidly becomes worse, and six hours later the systemic symptoms are often greatly accentuated. The patient becomes profoundly toxic, with high temperature, delirium and dyspnea. Locally, in typical cases, the part is swollen, tender, tense, and often bronzed in patches; the surface, however, may look and feel normal. A tympanic note on finger percussion, as emphasized by Lemaître, can often be demonstrated. Crepitation is frequently present. On opening the wound, or perhaps not until the aponeurosis has been opened, bubbles of gas and thin, brownish fluid exude; the typical rotten meat smell is noted, and the involved muscle shows the characteristic appearance and lack of vitality, notably, an unhealthy salmon color, friability and failure to contract on pinching. Cultures in these cases show various anaerobes, especially *B. welchii* (*perfringens*),

often associated with pyogenic organisms. Tissier believes that the association of anaerobes and streptococci is necessary for the development of gas bacillus infection. Other bacteriologists, however, question this.

Lemaître presents the following results of primary suture:

1. Wounds of the soft parts of medium importance, seventy-one, with three total failures and eight partial failures.

2. Wounds of the soft parts of greater importance, 106, with twelve complete failures and nineteen partial failures.

3. Wounds of the soft parts with injury to a large nerve trunk, thirty-four, with no complete failures and four partial failures. By complete failure he means necessity for removing all stitches; by partial failure, superficial infection necessitating removal of a few stitches.

In ninety-nine cases of primary sutures of wounds of the soft parts made by my team at Evacuation Hospital No. 1, there were ninety-three successes and six failures. This was approximately the percentage obtained by the other teams.

DELAYED PRIMARY AND SECONDARY SUTURE

Let us now consider those wounds which are not closed by primary suture.

Dressing for Wounds Left Open After Primary Operation.—After debridement the wound is dressed. The following routine has proved satisfactory:

1. In cases in which the patient is to be evacuated, petrolatum gauze or other brand nonadhering gauze is placed along the edges of the wound so as to cover the skin edges and subcutaneous tissues. This keeps the dressing from adhering and lessens hemorrhage and pain on its removal. Gauze soaked in surgical solution of chlorinated soda (Dakin's solution) is placed very loosely in the wound. It should be so adjusted as not to cork the wound so that excretions are retained.

2. Cases which are to be retained may be dressed as described above, or the Carrel-Dakin treatment may be begun at once in selected cases.

Indications for the Use of the Carrel-Dakin Treatment.—1. If a wound is likely to be susceptible of delayed primary suture, it does not need chemical disinfection, and the Carrel-Dakin treatment is not used.

2. If a wound is not likely to be susceptible of delayed primary suture, in other words, if it must be left open for a considerable time, for instance, a week or more, infection will probably result. The use of Carrel-Dakin treatment will prevent or limit infection. Its employment in such cases is advisable.

3. When infection has occurred, the Carrel-Dakin treatment will do much to control and terminate it. The treatment under these conditions is essential.

Delayed Primary Suture.—The distinction between delayed primary suture and secondary suture is one of tissue repair rather than of time. Delayed primary suture is one in which the edges can be approximated and will unite without excision of tissue. Secondary suture is one in which the epidermis has grown inward and must be excised for proper union. This is, in general, about one week. In late secondary sutures, dense granulation tissue must also be excised. The

determination as to when a wound may be sutured depends on bacteriologic findings and clinical observation. It must be emphasized that the cooperation of a bacteriologist is indispensable in making a decision as to the indications for delayed primary and secondary sutures. The practical function and indisputable importance of the bacteriologist in war surgery lies in this. In the consideration as to whether a wound is suturable or not, reliance must be placed chiefly on cultures, the important feature being the determination of the presence or absence of hemolytic cocci. For this, a routine blood-agar examination is essential.

Bacterial counts are far from exact, yet they give an indication as to the degree of bacterial contamination of a wound, especially the progress from day to day, and are of value especially for one untrained in estimating clinically the indications and contraindications for suture.

From eighteen to twenty-four hours after the original operation of debridement or excision of tissues, the wound is dressed and a culture and a smear are made. A report is returned as soon as possible. If no organisms are found, suture is indicated. If hemolytic cocci are present, suture is not considered. In the absence of hemolytic cocci, if the wound is clinically suturable, the presence of a few anaerobes or other organisms (approximately one in two fields) does not contraindicate suture. A considerable number of organisms of any kind indicates the necessity for caution. Suture, in that event, should be delayed and a culture and a smear repeated at the following dressing.

Delayed primary suture is usually made within six days after the primary operation. The advantages are the practical elimination of the danger of gas bacillus infection and the marked lessening of the danger of pyogenic infection. The disadvantages are the possibility of postoperative contamination of the open wound and the subjection of the patient to a second operation, with the attending discomfort and danger of postoperative complications, such as pneumonia. These disadvantages, however, do not equalize the risk incurred by primary suture in doubtful cases.

Technic of Delayed Primary Suture: All dressings of wounds after the primary operation should be made according to the Carrel-Dakin technic. The antepreparative preparation of the wound for delayed primary suture consists in painting the skin with tincture of iodine, after thorough cleansing as in the routine dressing. Some operators also paint the wound surfaces.

The details of suture are the same as for primary suture.

Secondary Suture.—The following is the routine generally followed: After forty-eight hours, at the daily dressing, a culture and a smear are made. The first report, therefore, contains the approximate number of organisms per field and the varieties of organisms. Thereafter, a smear is made every two days. It is also advisable to make a culture occasionally. Care must be taken not to touch the skin surface in making the smear, since skin contamination vitiates the value of the report. From the smear a bacterial curve is plotted according to Carrel's plan. When the organisms in two successive counts are few, that is, approximately one per two fields, and a culture shows an absence of hemolytic cocci, the wound is considered susceptible of secondary suture, except when the wound has contained hemolytic cocci at any time. In that case careful cultures are made from granulation

tissue and from the discharge from all parts of the wound; and absence of hemolytic cocci should be established by two successive negative cultures before suture is made. It has been observed that streptococci are prone to lie dormant in small numbers, but to flare up and cause virulent infection after closure of the wound.

Technic: The preparation is the same as for delayed primary suture. Lemaître distinguishes two varieties of secondary suture:

1. Secondary suture of the skin. The incision surrounds the new epidermis along the wound edges. A healthy normal skin edge must be present for successful suture. The skin is freed by undermining in all directions, as far as necessary, in order to approximate the edges with the minimum tension. This separation is made in the plane immediately superficial to the deep fascia. Only dense scar tissue or projections of granulation tissue are removed from the wound. The deep fascia is then approximated with interrupted catgut when possible; usually this may be done in the thigh and shoulder, but rarely in the leg, arm and forearm. The skin and subcutaneous tissues are closed with silkworm gut. Considerable tension may be allowed, for more than we are in the habit of permitting in civil practice. If little skin was removed at the original operation, the skin stretches in a short time, tension is relieved, and good union results. The result of suture is directly proportionate to the degree of tension. If there is extreme tension, infection may be expected. It is surprising, however, how well most of these wounds do, even after some infection. After the suture is completed, a dry dressing is applied with considerable pressure and left undisturbed, if conditions warrant, for about eight days, after which sutures are removed.

2. Secondary suture reconstruction. The granulation tissue and scar tissue are removed from the entire wound, and all layers are reconstructed by suture.

When two longitudinal wounds are on the same transverse plane, with considerable loss of tissue in each, one wound can usually be closed completely and the other closed in part. A dry dressing is applied, and the wounds are left for about eight days, after which the sutures are removed. The unclosed portion then presents a flat, clean granulating surface.

WOUNDS OF THE FACE

Wounds of the face must be considered independently. However severe, extensive and dirty the wound, virulent pyogenic infection or gas bacillus infection are not prone to develop. This feature makes it possible, by timely operative intervention, to avoid in most cases the gruesome mutilations which were so often allowed to occur in the early days of the war. The rule which may be followed safely is to repair wounds of the face as soon as possible after the receipt of the injury without general excision of the tissues. The wound is cleaned thoroughly, and only such tissue is removed as is definitely devitalized.

WOUNDS OTHER THAN THOSE OF THE SOFT PARTS

In regard to suture in wounds other than those of the soft parts, we must touch on suture in compound fractures and in wounds of joints. Wounds of the abdomen, thorax and skull cannot be dealt with adequately in a general review of the subject of suture, since each demands specialized consideration.

Compound Fractures Caused by Projectiles.—In compound fractures caused by projectiles, the same indications for operation must be followed as in wounds of the soft parts alone. Operation, therefore, is performed in all cases except through and through wounds by bullets, with punctate wounds of entrance and exit and little or no ecchymosis, swelling and tension of the parts. Such fractures are not markedly comminuted, and it has been found that this type usually does best without operation.

In the operation, the wounds of the soft parts must be subjected to the same primary treatment, that is, débridement, as wounds uncomplicated by fracture. The bone complication simply accentuates the importance of expedition, thoroughness and early closure. The last is especially important because it means the conversion of an open into a closed fracture.

The fracture should ordinarily be freely exposed. Small fragments which are encountered in the débridement of the soft parts, and large fragments which are completely detached, should be removed; but the temptation to remove fragments freely should be resisted. It is important that attached fragments be conserved. The bone is cleansed as well as possible, but débridement of the tract through the bone cannot be as thorough as that of the soft parts.

The subsequent treatment of the wound, after the primary operation of débridement, comes under the same general rules as apply to wounds of the soft parts alone. Primary, delayed primary or secondary suture may be made, and the Carrel-Dakin solution may be employed as in wounds without fracture. In the consideration of the closure of such wounds, it must be recognized that the laceration of soft parts is extensive in most comminuted fractures of the extremities, not only on account of the injury by the projectile, but also as the result of bone fragments scattered through the adjacent muscles. The chief danger of primary suture is the development of gas bacillus infection due to anaerobes and favored by incomplete débridement, muscles devitalized by vascular injury or the presence of foreign bodies. In the event of infection, moreover, the fracture exposes to the danger of osteomyelitis with the consequent increased danger of life, limb and function.

The development of osteomyelitis, particularly osteomyelitis of a serious grade, is favored by a closed infected wound, especially if the case is not carefully watched and the wound not immediately reopened should infection develop. Therefore, the advantages of delayed primary suture over immediate suture, and the disadvantages of primary closure when the operation must be done hurriedly or the patient must be transferred soon into other hands, are even more striking in the case of compound fractures than in wounds of the soft parts without fracture. In addition to the treatment of the wound, provision must also be made, in all these cases for reduction and immobilization of the fracture by external splinting.

Primary suture may be safely performed in some cases of compound fractures caused by projectiles, as we noted at La Panne and in our own service. The practice is dangerous, however, except rarely in early cases with little involvement of soft parts and bone. I am convinced that delayed primary suture should be aimed at in most compound fractures of the long bones under conditions in which the patient can be properly operated on and watched thereafter. It has been dem-

onstrated repeatedly that bad fractures of all the long bones except the femur may be closed in from three to six days after débridement, thus converting them into simple fractures. Moreover, this can be done with few failures and little risk. If delayed primary suture is not possible, secondary suture often may be made successfully.

The details of the dressings are the same as already described for wounds of the soft parts. If, at the primary operation, early suture seems probable, Carrel-Dakin treatment is not used, because experience has shown it to be unnecessary and probably, at times, harmful by reason of the fact that the wet dressings must be changed, which often necessitates moving the fragments which should be studiously immobilized from the outset.

It must be emphasized that early suture can be undertaken only in relatively quiet periods and in hospitals in which the patients can be kept and carefully observed.

Wounds of Joints.—The principles of treatment, in wounds of joints, are complete débridement of the tract of the projectile through the soft parts and bone; removal of foreign bodies; irrigation of the joint, first with saline solution, then by distention of the joint with ether; absolute closure of the joint by suture, with or without closure of the superficial parts according to the rules laid down for primary suture of the soft parts alone, and finally, early active motion.

An effort should be made to save the joint, provided the conservable articular surfaces and soft parts are sufficient to warrant a reasonable hope of securing a useful joint.

If an attempt is to be made to save the joint in a case in which there is such destruction of soft parts that the capsule cannot be completely closed, the defect in the capsule should be closed with muscle or fascia.

After-Treatment: If the joint becomes distended, and infection is suspected, the effusion should be aspirated immediately and a culture made. If the patient's condition, the local examination, or the character or culture of the aspirated fluid indicate pyogenic infection, lateral incisions should be made at once; or if the original incision is so placed as to allow satisfactory drainage, it should be reopened and the treatment for suppurative arthritis begun.

APPLICATION IN CIVIL SURGERY

Primary and secondary sutures have a real application in civil surgery: for instance, primary suture in compound fractures and wounds of joints, and secondary suture in various conditions, but especially for the closure of suppurating wounds which have been disinfected by the Carrel-Dakin method.

107 East Sixtieth Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LEWIS AND POOL

DR. FREDERICK W. BAILEY, St. Louis: The question of débridement so ably covered by Dr. Lewis leaves little to be said. The chief essentials are to remove all the devitalized tissues—scientifically, not roughly. Rough dissection is perfectly proper where the anatomic structures will permit it, but in areas around the larger vessels and nerves débridement should be done just as carefully as any other surgical operation in civil life. In the general hospitals at home we are at present engaged principally in undoing a great many of the mistakes which were made on the other

side. I do not doubt but that a fair number of nerve sutures, a fair percentage of them, are probably due to careless surgery during the original débridement in the field or evacuation hospital. I think all of us could point to instances where carelessness in débridement caused the loss of a limb through the destruction of the arterial supply. The place where we should begin our reconstruction work is at the front. It would make it easier for the general hospitals and base hospitals after the work has been finished.

Débridement of the bone has been sadly neglected. Many of the cases which are now causing a great deal of trouble and which will be on our hands for an indefinite time could have been prevented had the bone been débrided at the original operation. They have set up an osteomyelitis which extended and made subsequent operation more difficult than if it had been attended to properly at the time of the first treatment. As regards primary suture, I cannot give you any information in that line. The work at the advanced station, in my opinion, does not justify primary suture by the surgeons who are available in these places. Very seldom, especially in times of stress during great activity, were we able to see our patient more than once in three days. Often the patient was whisked away in a few hours. Primary suture should not be attempted unless the surgeon who attempts it can watch the patient for an indefinite number of days. As to the exposure of these cases in regard to débridement: In cancer an exposure is necessary, especially when the tumor is situated in the deeper tissues and nerves. We hope we shall never again have to do this type of work, but if we do, we should have capable surgeons at the front, men who will eliminate much of the suffering and loss of life at the front and shorten the reconstruction work in which we are now engaged.

DR. FENTON B. TURCK, New York: As Dr. Murphy's assistant I carried out some investigations on the cause of death without infection. I found that injecting peptones caused death of the animal in three minutes. I published this work in 1897 and called it "The Toxines of Shock." In 1903 we obtained the same material from the abdominal cavity and walls of the intestines and it produced immediate death from shock. In 1912 I introduced muscle tissue from autolyzed tissue. We found germs growing in the wounds that produced the reactions in the lung and in the upper alimentary tract. We made antigen, injected it into animals and prevented the death of the animals which is due not to wounds but to autolysis. I want the surgeons to understand that autolysis is the real cause of death and not the toxines or germs. Dog's tissue will not kill cats, but dog's tissue will kill dogs and cat's tissue will kill cats. It is a species of reaction.

DR. DONALD MACRAE, JR., Council Bluffs, Iowa: I sometimes fear that men may get an impression that débridement means cutting out the entire wound, similar to removal of a carcinoma, and I have seen this done on numerous occasions. This is not the idea of débridement. The idea is not to take out tissue en masse, unless the tissue is dead. It is not necessary to gouge out the muscle and hunt for vitalized tissue, which may be very close to the surface.

It was my privilege to be on the Château Thierry front when we did not have teams, with 1,200 and 1,300 wounded lying on the ground and no one to take care of them. The average men coming up, good and bad surgeons of the United States, knew very little about débridement and yet it was known by the British and French. Why didn't we know it? So it seems to me in talking of preparedness and getting ahead of the game in our profession, and of gas gangrene, that we would have gotten ahead of the game if we could have known about débridement before and been able to do débridement immediately on our arrival on the field.

DR. W. M. THOMPSON, Chicago: I would like to add my testimony to the remarks of the previous speaker. After a continued sojourn in France, working with three armies, I think I have had almost as much experience as any American in débridement. We have had some splendid papers on the subject, but even after reading these papers

and reading all the literature on this subject no man is competent to do débridement correctly. It must be seen; you must live it; you must live in the atmosphere of it. Our surgeons made mistakes in France not because they were incompetent, but because they were not given the opportunity to see these things and learn about them first hand.

DR. KELLOGG SPEED, Chicago: This is the time to get primary impressions. I do not like what Dr. Macrae said about Château Thierry and the surgeons—good, bad and indifferent—that were there. The articles I have written on war surgery were put out with considerable effort, with a great deal of pleasure, with hopes that men would use them and profit by them. I had had experience before we entered the war, and I was with one of the first units that touched France in 1917. I arrived in connection with the MacKae outfit, June 5, 1918. I knew about débridement. I had done hundreds of such operations. There were a few other men there who knew about débridement. There was in these organizations—not citing Colonel MacKae's as one—a lack of seasoned men such as there were to be had in France. There were scattered through the English forces and through the French, men who did know these things and who wanted an opportunity to go ahead and practice what they knew, but a large percentage of them never had a chance to do it and when they were sent over, as I was, they were put in entirely subsidiary places that did not count.

DR. DIAN D. LEWIS, Chicago: The strange thing about this subject is that patients with the devitalized muscles have the least shock. The shock cases are those of gunshot wound through the knees, the cases in which the legs are practically shot off. With all this theory of peptones in the production of shock, and I do not care how long this has been in circulation, certain clinical factors demonstrate that you can have all the contused muscle you want until gas gangrene develops and the patient does not suffer from shock. Another thing about débridement's not being known by American surgeons: They understood the principles of it. The only way you can learn to do it is to do it. If we ever have another war I hope the evacuation hospital is made the center for instruction for surgeons who are going to practice surgery. They should be there as observers and train younger men. You could not learn débridement in Fort Riley or Camp Greenleaf, but you can learn the principles, that is, a thorough knowledge of anatomy. If a man has a thorough knowledge of anatomy, with good sense and judgment, he will learn how to do débridement. The thing that impressed me in our American Expeditionary Force was that we have been developing physiologic surgeons. The war demanded that we have anatomic surgeons, but they were few.

New York Indians a Health Problem. The April number of the *Monthly Bulletin* of the New York State Department of Health is entitled the "Indian Conference Number." It describes the health problems in connection with the Indian population of this state. The state health department has also issued a special bulletin on this subject. New York state has an Indian population of more than 5000; these Indians come in close contact with a million or more white citizens in the neighborhood of the reservations. A bill has recently been signed by the governor providing for a state commission to confer with the Indian committees of the two houses of Congress in an effort to better the situation. The Indian has adopted the white man's way of living in houses, but does not pay the same attention to light, ventilation and other sanitary factors. Consequently he falls an easy victim to tuberculosis and is prone to acquire other communicable diseases and to spread them among his white neighbors. The department has recently made a sanitary survey of the Onondaga Reservation. The results show the need of teaching the Indian sanitation and personal hygiene. The survey will be extended to other reservations in the state as a preliminary step to the development of a comprehensive system of instruction in sanitation. At present the Indians are under the charge of the national government.

TRENDELENBURG ANESTHESIA IN SURGERY OF THE PELVIS*

DONALD GUTHRIE, M.D.

SAYRE, PA.

I am convinced that the Trendelenburg¹ method of anesthetizing plays an important rôle in the prevention of postoperative ileus and shock, and therefore believe it worthy of consideration by this section.

Fig. 1.—Patient's legs strapped to foot of table by a broad surcingle.

It is a well known fact that trauma to the small intestine is one of the direct causes of postoperative shock and ileus. An experienced surgeon can often predict just which patient is going to have a stormy convalescence by the amount of trauma the small intestine has, of necessity, been subjected to during the operation; for trauma to the small intestine differs very much in its harmful effects from trauma to the other intra-abdominal organs. Indeed, some of the

Fig. 2. Anesthesia begun with patient in high Trendelenburg position.

most comfortable patients we see after operation are those who have had resections of the large intestine, or extensive operations on the stomach, and some of the sickest are those with the quiet distended abdomens, regurgitation, restlessness and fast pulse—symptoms hard to differentiate from a beginning peritonitis.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

1. Guthrie, Donald: Factors of Safety in Abdominal Hysterectomy, *Am. J. Surg.* 33: 49 (April) 1919.

or a mechanical obstruction of the bowels, and which are the result of extensive trauma to the small intestine by the use of packs, made necessary to get exposure of the operative field.

Briefly, the object of the method is to rid the pelvis of as much of the small intestine as possible before the abdomen is opened for an operation in the pelvis. It is best employed for ether anesthesia, although I have used it with a fair degree of success during gas-oxygen anesthesia. The anesthesia is started with the

patient in the high Trendelenburg position (Figs. 1 and 2) on the operating table. It is not necessary to have patients who object come into the operating room to be anesthetized, although with the proper kind of anesthetizers very few patients will object. If the anesthetic is given in an anesthetizing room, the patient is put on the table which is to be used

Fig. 3.—Lifting abdominal wall to free pelvis of any coil of small intestine.

during the operation, and the anesthesia is started with the patient in the high Trendelenburg position. The method cannot be employed successfully except by a skilled anesthetist, one who is well trained in suggestion and who can quiet the most apprehensive patient and quickly allay her fears, for the objections to the method are that it may frighten the patient and that the position may be uncomfortable.

It has been asked why it is not possible to begin the anesthesia in the dorsal position and change to the Trendelenburg position as the patient is getting under the anesthetic, or to wait until the patient is fully anesthetized and then change to the Trendelenburg position before making the incision. I have tried both these methods, and in my hands they do not work with the same success as the method I am advocating. To change the patient's position as she is getting under the influence of the anesthetic frightens her, I have found, and starts straining or coughing, either of which is fatal to the success of the method. To wait until the patient is fully anesthetized and then change her position does not give the diaphragm time enough to pull the intestine out of the pelvis.

The anesthetist, who has previously met the patient, accompanies her to the operating room, feeding her mind with well chosen suggestion. The patient steps on a stool and sits on the table, the foot part of which has been lowered. The legs are fastened to the foot of the table by a broad sureingle which is fitted snugly, but not made uncomfortably tight (Fig. 1). The patient then lies down on the table with her hands clasped and her arms folded across her chest. The arms are fastened by a gauze bandage, which is attached to the head of the table. The table is now lowered in the high Trendelenburg position and the anesthesia begun (Fig. 2). Absolute quiet is maintained in the operating room while the anesthetic is

given. The patient's attention is left entirely with the anesthetist.

If the anesthetic has been given successfully and the patient has not strained or coughed while going to sleep, it is usual to find only a coil or two of small intestine in the pelvis, provided, of course, the intestine is not adherent to the pelvic structures. Through a small opening in the peritoneum, two fingers of the right hand are inserted into the cavity, and the abdominal walls are well lifted up (Fig. 3). The intruding air will cause any coils of intestine which have not gravitated out of the pelvis to slide upward, so that it is usually necessary to employ only one small gauze square to get excellent exposure (Fig. 4).

In comparing this method with the one usually employed, that of anesthetizing the patient in the dorsal position, making the incision and then calling for the Trendelenburg position (Fig. 5), it is amazing to see the difference in the amount of gauze packing necessary to use to obtain exposure (Fig. 6).

ABSTRACT OF DISCUSSION

DR. JOHN OSBORN POLAK, New York: It is a privilege to endorse what Dr. Guthrie said of the advantages of etherization in the extreme Trendelenburg posture as suggested by him. Those of us who have seen the foreign operators have been impressed with the facility with which they operate on the pelvic organs. The two points which make operation on the pelvic organs easy are, first, proper exposure of the pelvis by posture and, second, sufficient exposure of the field by a

Fig. 4.—Exposure of pelvis, only one small square of gauze being necessary.

large incision. Whether these pads be the gauze roll, or whether they be individual pads, or whether they be protected with gutta-percha tissue as suggested by some, they all produce trauma. If any of you have taken the trouble to investigate the experimental use of gauze on the peritoneum of animals you will know this to be true. What Dr. Guthrie said is absolutely true, that the postoperative convalescence is dependent on the amount of trauma done to the small intestine. The usual transfer of the patient from the anesthetizing carriage to the operating table is not only an unnecessary waste of ether, for it disturbs the patient who is awakened

from her light anesthesia and we have greater difficulty in securing sufficient relaxation. Consequently the operating table should be mounted with large wheels so that the patient may be anesthetized in this position on the table for pelvic operations. There is one criticism that I would make; I do not know that I have any ground for it. Instead of flexing the legs on the thigh and maintaining the patient in position by fastening the legs to the table which we feel causes tension of the rectus muscles and require deeper anesthesia, we have been having the legs extended and the weight of the body supported by the shoulders which are held in place by well padded shoulder pieces. When the patient is in this Trendelenburg posture I do not believe this posture can be used from the beginning as satisfactorily with the combination gas oxygen as with ether. The nitrous oxid-oxygen men tell us that they have educated the surgeon to operate with tense muscles. We feel that in operating we can get the needed amount of relaxation with minimum anesthesia if the patient is not disturbed during the induction of the anesthesia and this posture is used from the beginning of the anesthesia.

DR. ALBERT J. OCHSNER, Chicago: As to the time at which the foot of the bed is to be elevated, I would say that it does not matter so much so long as the table is elevated several minutes before the operation is begun. Bell of Montreal directed attention to the fact that when he anesthetized patients in the moderate Trendelenburg posture they did not inspire any mucus, and consequently at that time when most surgeons had many cases of ether pneumonia he had none. Of course, the inspiration of mucus does not begin until the patient is fairly well anesthetized because the patient protects herself before that time by swallowing the mucus, so that this feature will be equally well taken care

when the operating table is wheeled into the operating room. We have an anesthetizing room and then wheel the patient into the operating room and then the foot of the bed is immediately elevated. I am absolutely sure that Dr. Guthrie's plan is of tremendous value.

Fig. 6.—Trendelenburg anesthesia: coils of small intestine gravitated out of pelvis when patient is anesthetized in this position.

Fig. 5.—Compare difference in amount of small intestine in pelvis when patient is anesthetized in the dorsal position.

of if the patient is completely anesthetized in the horizontal position, and then before the ultimate preparations are made for the operation the foot of the bed is elevated, but you can tell the difference every time in the position of the intestines in patients remaining in the horizontal position until the abdomen is opened. For twenty years I have invariably directed that the foot of the bed be elevated

DR. DONALD C. BALFOUR, Rochester, Minn.: Dr. Guthrie had brought out a point in operative procedure that can well be kept in mind at all times. We follow out practically the same practice. We make the time a little later in which the patient is put in the Trendelenburg position, that is, as soon as the patient is unconscious of what is going on. In the majority of cases there is then sufficient time for the pelvis to be practically clear of small intestine. In my own observation much trauma is occasionally caused because of the impatience of the surgeon. Instead of being willing to wait until the patient is well relaxed and the intestines can easily be blocked off from the pelvis by gauze, their impatience is so great that while the patient is straining they try to force the intestines into the abdominal cavity rather than waiting for good relaxation.

DR. DONALD GUTHRIE, Sayre, Pa.: I would like to emphasize two points. First, the method of lifting the abdominal walls up after the peritoneum is opened. Any coils of intestine that have not gravitated out of the pelvis during the anesthesia can, as a rule, be made to slide upward. Second, I believe that we can get better results in fully anesthetizing patients in the Trendelenburg posture rather than to anesthetize them in the dorsal position and then change to the Trendelenburg position before the abdomen is opened, as mentioned by Dr. Balfour. This method cannot be employed successfully except by a skilled anesthetist, who is well trained in suggestion.

Entomology and Disease.—An outstanding feature of the louse and bedbug studies is the fact that these insects do not spread disease by biting but by being scratched into the flesh or having their feces scratched into the flesh. The importance of these studies must not be minimized for quite possibly we have here a profitable explanation of the means of ingress for a number of other diseases which have baffled investigators. W. D. Pierce, *J. Econ. Ent.* 22:43, 1919.

ABDOMINAL SURGERY UNDER LOCAL
ANESTHESIA *ROBERT EMMETT FARR, M.D.
MINNEAPOLIS

The literature on local anesthesia deals so uniformly with arguments regarding the merits of local as compared with general anesthesia that one hesitates to bring up for discussion that phase of the subject. The personal equation, however, enters so largely into the question that the advantage of one over the other, aside from the element of safety, will depend to a great extent on the experience of the operator. Those who are for any reason unable successfully to perform a large variety of operations under local anesthesia are at once a unit in deciding that general anesthesia has more advantages. On the other hand, those who can with satisfaction perform a large variety of operations by the local method will be found to hold the opposite view. It must be admitted that at the present time a vast majority of surgeons believe that general anesthesia is the method of choice, and that local anesthesia should be reserved for minor and for extreme cases. That sentiment is undergoing a rapid change in favor of local anesthesia must be admitted also. It is my belief that the opinion of a surgeon regarding the relative merits of the two methods will vary in accordance with his experience, and that the more experience one has with local anesthesia, the more successful he will be with it and the more enthusiastic he will become regarding its use. I believe that local anesthesia represents one of the greatest advances of the time, and

ADVANTAGES OF LOCAL ANESTHESIA

I shall enumerate some of the advantages of local over general anesthesia, and reserve the balance of the time allotted me for a consideration of the methods which, in our hands, have given satisfaction.

Fig. 2.—Pneumatic injector, "set up," filled and ready for use. Note sterile towel, protecting tubing. By turning down the upper end of this towel we develop the diaphragm shown in Figures 5 and 7.

First of all, the one great advantage of local over general anesthesia is that of safety. That procain is safer than any of the general anesthetics is, I believe, admitted by all. The other main points to be considered relate to the comfort of the patient and the efficiency of the anesthesia. There is some question as to which of these two points should be considered the more important. While the comfort of the patient is an extremely important matter, I consider the manner of performing the operation of even greater consequence. I wish, therefore, to call attention to some significant factors relating to the efficiency of an operation performed under local as compared with one performed under general anesthesia.

In all operations one is confronted with the consideration of such factors as hemorrhage, sepsis, trauma, exposure, time and shock. These factors are not necessarily mentioned in the order of their importance; as a matter of fact, their relative importance varies in different operations. I wish briefly to consider each one of these factors in relation to these two methods of anesthesia.

Hemorrhage.—It is pretty definitely established that shock bears a direct relation to the amount of blood lost during an operation. In local anesthesia, the use of epinephrin and the possibility of doing more deliberate work give one a control over the blood supply that is superior to that offered under general anesthesia. Another factor which is not fully appreciated by those who do not do a fairly large amount of local work is the turgescence of the vessels, especially

Fig. 1.—Pneumatic injector: A, glass cylinders for procain; B, pressure tank for compressed air; C, motor; D, rheostat; E, compression pump; F, cotton filter; G, air gage; H, valves; J, flexible metal tubing; J, cutoff; K, needle; L, suction bottle; M, rubber tubing for suction; N, suction tip; N, towel rack.

that, provided no other method is discovered to supplant general anesthesia, the latter will to a large degree be replaced by the local method.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

in the venous system, when general anesthesia is used. This is especially noticeable in work about the neck and head, and is also markedly apparent in abdominal work. The distended and engorged vessels so frequently seen during general anesthesia are uniformly collapsed during local anesthesia.

Fig. 3.—Pneumatic injector, cutoff and suction tubing within easy reach of surgeon's hand, and separated from the injector and anesthetic by sterile towel.

Sepsis.—The dangers from sepsis probably differ very lightly in the two forms of anesthesia. To my mind, however, what advantage exists is in favor of local anesthesia, for the reason that operations performed under local anesthesia may be done more deliberately and with more attention to detail than is possible when general anesthesia is used. In abdominal work, especially, the excursion of the abdominal viscera with respiration, during general anesthesia, is oftentimes marked, and may cause considerable embarrassment. The placid condition of the viscera under local anesthesia possibly gives one technical advantages. In the case of localized abdominal infections, for instance, it is not uncommon to see a spread of the infection result from the struggles of the patient while going under or emerging from general anesthesia; and I myself have witnessed a number of cases in which localized abscesses had ruptured internally during anesthetization or at operation. On the other hand, with a perfect local anesthesia and careful handling of a patient I have never seen this accident occur. During operation, abdominal packs may be introduced without danger of rupturing an abscess, and after operation the perfect physical rest attained aids in preventing the spread of a septic process. Postoperative vomiting and restlessness undoubtedly interfere with nature's process of localizing abdominal infections.

Trauma.—One of the greatest advances in surgical technique of the last two decades has resulted from the realization that the tissues should be traumatized as little as possible during surgical operations. To local anesthesia, and to those who have employed it, must

largely go the credit for this advance. Sepsis and morbidity following operations are closely related to the degree of trauma inflicted during operation. I am sorry to say that one still sees, all too frequently, a violation of the principle that the tissues should be traumatized as slightly as possible, and in this regard those using local anesthesia are not the offenders, but are, as a class, leaders in teaching the necessity of delicate handling of the tissues.

Exposure.—When one observes the exposure that may be obtained in abdominal work under a good infiltration anesthesia, resulting in a negative intra-abdominal pressure, with the viscera retracting from the laparotomy wound instead of extruding through it; when one sees organs lying in their natural position, devoid of engorgement and motion, he must at once realize that nothing but the most profound general or spinal anesthesia will give as good an opportunity for inspection and operative work in this region. True, the viscera may not be delivered or displaced and handled as readily; distant digital explorations are not so easily made, and adherent masses are not so easily dealt with. If we confine the use of local anesthesia, however, to the class of cases in which it is indicated, and if we agree that, to a large extent, visual rather than digital exploration should be made within the abdominal cavity, local anesthesia compares favorably in offering adequate exposure.

Time.—The element of time quite naturally presents itself along with the other factors. The argument so frequently presented that the excess of time required for local over general anesthesia cannot be spared by the surgeon should, it seems to me, be unworthy of consideration. I wish to consider the element of time only in relation to the patient's welfare. Other things being equal, it will, I think, be admitted that an operation which is done deliberately will receive more atten-

Fig. 4.—Apparatus in use: Abdominal tumor delivered. Relative positions of anesthetist, patient, surgeon, pressure and suction tubing, with sterile towel as diaphragm, definitely isolating the operative field. Injector is to the right, outside the field of the illustration.

tion to detail and be performed with more finesse than when the surgeon is making every effort to finish the operation as quickly as possible. A consideration of this feature must surely result in findings in favor of local over general anesthesia.

Shock.—Assuming that the amount of hemorrhage and trauma are reduced by the use of local anesthesia,

the natural inference would be that there would be less shock following operations performed under local anesthesia. This is undoubtedly true and this fact is, I think, recognized by all. It will take but a small series of major abdominal operations performed under local anesthesia to convince anyone that the condition of the patients following these operations is not to be compared with the condition we are accustomed to see after serious abdominal sections performed under general

change to general without hesitancy when it is advisable.

A discourse on this subject would be incomplete without a reference to the question of local anesthesia in children. In our experience, abdominal operations may be performed on children with as great facility as on adults, or even greater. We have repeatedly made laparotomies on very young children without signs of distress from the time the abdomen was opened until the closure was made. In two recent cases of hypertrophic pyloric stenosis, in babies under 6 weeks of age, the entire operation was completed without an outcry or expulsive effort on the part of the baby. This operation, which is considered a serious one, is by this method converted into what might be called a minor procedure, which may be carried out with almost ridiculous ease.

TECHNIC

The local anesthetic of choice is procain, 0.5 per cent. in Ringer's solution, combined with epinephrin, 5 drops to the ounce.

In all except hernia cases we depend on a direct infiltration of the abdominal wall rather than on a conduction anesthesia. All layers of the abdominal wall are infiltrated before the incision is made. We consider the necessity of supplementary injection of procain as an indication that our technic has been faulty.

In making the infiltration, minute attention is given to details. The ideal aimed at is to deposit the fluid equally throughout the desired area without any sensation of pain on the part of the patient after the first needle prick, which is made for the production of the initial intradermal wheal. All subsequent wheals are made from beneath (Fig. 5), and the intradermal wheal is repeated only for the purpose of secondary introductions of the infiltrating needle as the field is traversed. Aside from the wheal points, the skin is anesthetized by a subdermal infiltration. A 4-inch record needle, No. 23, is used. Through this a wall of infiltration is built beneath the proposed line of incision, with a base of from 2 to 3 inches in width, the apex being the line of incision through the skin (Fig. 6).

Equipment.—Ten years ago we discarded the syringe and substituted the pneumatic injector (Figs. 1, 2 and 3) for this work. This apparatus gives us a constant flow of the solution with a steady pressure controlled by a cutoff, which is ideal from the standpoint of ease of manipulation. With this instrument the ordinary abdominal wall can be anesthetized in from two to three minutes, and, as the incision may be made immediately, much time is saved. The average time, from the beginning of the administration of the anesthetic until the abdomen is opened, is from five to seven minutes. Throughout

Fig. 5.—Sectional views of the skin: *a*, method of making first dermal wheal; *b*, needle subcutaneous method of making secondary wheals; *c*, method of making subdermal infiltration.

anesthesia, even though fairly careful technic has been followed in the latter. Three or four of these patients operated on during a morning can be cared for by a student nurse during the rest of the day, while she attends to her other duties, whereas few surgeons would be careless enough to leave any patient who has had general anesthesia without constant attendance on the part of a nurse for a few or perhaps several hours following the operation. The absence of thirst, nausea and vomiting, with their resultant dangers and disagreeableness, the low percentage of gas pains, which occur almost directly in proportion to the amount of trauma inflicted by abdominal packs and handling, are in marked contrast to that which takes place in patients who have been operated on under general anesthesia. I believe that surgeons have become so accustomed to feeling that the patient who must undergo a surgical operation is entitled to twelve, twenty-four or thirty-six hours of "hell" following it, that we do not appreciate the seriousness of the condition. Would it not be a good plan for every surgeon to spend occasionally the following twelve to twenty-four hours in the ward with several of the patients on whom he had operated under general anesthesia during the forenoon? The education obtained would almost equal that acquired by having the method applied to oneself.

The percentage of abdominal operations that may be performed with satisfaction under local anesthesia will, as I have already stated, depend largely on the experience of the operator. I have found that conditions which a few years ago I thought were amenable only to surgery under general anesthesia I now handle with the greatest ease and satisfaction under local anesthesia. The realization of the fact that operations begun under local may be finished under general anesthesia, in case it becomes necessary, has greatly increased the scope of the method. At present we begin all of our abdominal operations, regardless of the age of the patient, under procain anesthesia, and

Fig. 6.—Section of abdominal wall, showing area infiltrated.

this procedure every effort is made to eliminate the slightest sensation of pain on the part of the patient. If this is accomplished and the abdominal walls gently retracted vertically, the abdominal viscera will not protrude through the opening but will fall away from the field of operation, and, by making use of the force of gravity, all the viscera in the region of the incision may be examined visually without handling. Per contra, should the injection be carelessly or too rapidly made, or certain sensitive areas be missed in making the infiltration, and the incision thereby cause pain, there will be established a combative action on the part of the patient, and an expulsive effort which will cause an extrusion of some of the viscera. In the absence of acute infections and marked distention of the intestine, the viscera should not protrude through the abdominal wound in the presence of a perfect local anesthesia, unless, perhaps, the patient should inadvertently cough, sneeze or laugh.

Retraction of the Abdominal Wall.—Careless or vigorous retraction of the abdominal wall will also produce the expulsive effort which we wish to avoid. With the flaccid abdominal walls usually found under local anesthesia, only the mildest kind of retraction is necessary. I find that the most satisfactory retractor is the wire automatic, which gently and symmetrically spreads the incision (Fig. 7).

Sensitive Areas.—There has been considerable investigation concerning the sensations within the peritoneal cavity. Observations vary in this regard, and different patients seem to vary to some extent. The areas are more or less constant, however, in response to pain sense. We have found pressure and traction on the round ligaments of the uterus to be painful; and that the ovarian pedicles, the meso-appendix and the region of the cystic duct, are also sensitive. Traction on the mesentery is much more apt to cause nausea than acute pain, and one must be especially careful about making traction on the cecum and duodenum.

SCOPE OF LOCAL ANESTHESIA

Lower Abdomen.—All pelvic conditions of a simple nature may be handled under local anesthesia with great satisfaction. As a certain percentage of pelvic work, however, either is complicated by the sequelae of infectious processes or must be done to eradicate malignant disease, one encounters a fairly large percentage of cases that are difficult to handle under straight infiltration anesthesia.

Caudal Anesthesia.—For a number of years we have been testing a combined caudal anesthesia with an infiltration of the abdominal wall in conditions in which difficult pelvic work is anticipated. The anesthesia acquired in this way is usually ideal, and the complete Wertheim may be performed, or, in fact, any pelvic operation may be readily performed under the combined method.

The administration of procain by the caudal method is simple and is quickly given. In my experience, patients are more apt to show toxic symptoms when this form of anesthesia is employed than if infiltration only is used. A number of patients have shown pallor,

increased respiration and pulse rate, faintness and occasional nausea. While we have seen nothing to be alarmed about, I believe that the utmost care should be used in making the injection. It should be made through a flexible needle, which is not liable to break off in the canal, and the injection should be made slowly. A rapid injection will cause pain and is said to be more apt to cause toxic symptoms. Furthermore, one should avoid making the injection directly into the blood stream.

In the surgery of the bladder, prostate and pelvic organs this anesthesia is ideal, provided it is proved safe.

Above the pelvis we have had little difficulty in making intestinal resections, even with glandular involvement. We have performed several colectomies and colostomies, enterectomies and enterostomies. In the upper abdomen, the stomach, duodenum and gallbladder have most often been dealt with. With an adequate and properly placed incision, visual examination of this important region may be made with entire

satisfaction. We have made gastric resections for carcinoma and perforated ulcer, pylorotomies, gastrotomies and gastro-enterostomies under local anesthesia without the patients complaining of pain. Cholecystostomy is an exceedingly simple procedure, in most instances, under local anesthesia. When it comes to the removal of a gallbladder, we have been unable to develop a painless operation. We have, however, accomplished the removal in over 90 per cent. of our cases without resorting to general anesthesia, always allowing the patient the privilege of taking a general anesthetic if the distress becomes too marked. Traction on and clamping of the cystic duct is invariably painful, although in recent cases an infiltration between the gallbladder and the liver and about the cystic duct has rendered the operation almost painless.

Work on the common duct will depend entirely on its accessibility. We have removed stones from the common duct and explored this organ numerous times without the least difficulty. Of course, the presence of marked adhesions, with the retraction of the organ up behind the liver, will necessitate general anesthesia.

In gallbladder and duct work it is inadvisable to dislocate the liver, as is recommended for cases under general anesthesia. Instead of "up-ending" the liver outside of the abdominal cavity, we produce much the same effect by using blunt retractors on the liver edge and "up-ending" it beneath the ribs, thus bringing the gallbladder and ducts into view. During this procedure one pad of gauze holds the stomach and pylorus downward and to the right, while another pad is placed between the gallbladder and the duodenum. With perfect anesthesia, only slight retraction is necessary. If the anesthesia is incomplete, however, and the patient strains, nothing can be accomplished by the method.

One of the most satisfactory conditions to handle under local anesthesia has been extensive adhesions between the viscera or omentum and the abdominal wall. Ample incision and vertical retraction will allow the adherent viscera to hang from the abdominal wall in such a position that the adhesions may be divided

Fig. 7.—Automatic wire retractors.

on the white or bloodless line, and the most extensive work may be done with slight or no discomfort to the patient.

All plastic surgery on the abdominal wall, with or without adhesions, falls readily into the ideal class for local anesthesia.

One of the disconcerting factors in abdominal work under local anesthesia is the occasional vomiting of the patient. While this accident is generally due to some overt manipulation, it has to be reckoned with, and we have not been able entirely to eliminate it. This emergency has not arisen in more than 5 per cent. of our cases.

OBJECTIONS TO LOCAL ANESTHESIA

The objections to the local method are both real and imaginary. There is undoubtedly a class of cases in which general anesthesia should always be used. There is, I believe, also a class in which local anesthesia should always be used. That the latter class could be greatly increased with an improvement over the results obtained at present in the large clinics I also firmly believe. The objection that wide explorations cannot be made under local anesthesia is to some extent true, and yet it is to a large degree offset by the fact that wide explorations not made under the direction of the eye seldom give authentic information. How absurd it is, for instance, to see a surgeon extend his gloved hand to the region of the kidney and state that it is normal, and perhaps at the next operation deliver a kidney and spend a considerable time endeavoring to decide whether or not it is normal! Yet we see this absurd procedure carried out daily at many of our best clinics. Of course, a very advanced pathologic condition may be recognized by the introduction of the hand to some distant part of the abdomen; but there are few instances of this kind which cannot be diagnosed before the exploration is made, and, in cases in which the pathologic condition is not advanced, this method of examination is usually unsatisfactory. Furthermore, the introduction of the hand, under local anesthesia, is not an exceedingly painful procedure. With the abdominal wall elevated there is usually room to insert the hand and part of the arm with almost no contact with the surrounding tissues. It is my custom to examine the pelvic organs in gallbladder cases, and vice versa, although, for the reasons already mentioned, I feel that such examinations are possibly overrated with regard to their value.

Working under local anesthesia requires more time, but experience and proper equipment bring this much discussed factor into comparative insignificance. The strain on the surgeon is undoubtedly greater when working under local anesthesia; but if we accept the dictum that the all important factor is the patient's welfare, this objection must be eliminated; and the experience of the surgeon will here, again, make a decided difference. During recent years I find much more comfort in operating on patients under local than under general anesthesia.

CONCLUSION

The use of local anesthesia should no longer be confined to minor surgery and to cases in which the patient apparently cannot undergo the ordeal of taking a general anesthetic.

With proper equipment and technique, a large proportion of major surgery may be done under local anesthesia with greater safety, less trauma, more complete-

ness and less postoperative discomfort than when general anesthesia is employed.

Children lend themselves readily to the method.

The abdominal field presents a most excellent territory for the use of local anesthesia.

ABSTRACT OF DISCUSSION

DR. P. G. SKILLERN, JR., Philadelphia: The pneumatic injector devised by Dr. Farr greatly facilitates and accelerates the establishing of local anesthesia, since it does away with the necessity of picking up and putting down one syringe after another. I have used his apparatus with great satisfaction, and should call this method "operating de luxe." As emphasized and practiced by Dr. Crile, operating under local anesthesia develops a gentleness of touch and technique that is of benefit to the patient. I do not think that local anesthesia has made the progress in surgery it should. Every one ought to be using it today. It is wonderful to be able to operate on these patients, painlessly, without loss of conscience, and have them go back to their room and greet their friends immediately afterward. Surely this is better than the distressing picture we see so often after ether anesthesia, the patient unconscious, tossing about and vomiting in the presence of his anxious relatives and still facing the dangerous after-effects of ether, such as pneumonia, etc. Some claim pneumonia follows the use of local anesthesia, but I have never seen it and cannot figure how it could occur, provided the chest is protected from exposure. The point I wish to bring out very strongly is my belief that local anesthesia should be used—and that nothing else should be used—in a patient suffering from great toxic shock. The illustration, *par excellence*, is acute intestinal obstruction. The high mortality in acute intestinal obstruction is due to the patient already severely shocked from toxins having superimposed on that another toxin in the form of ether. The present high mortality of the acute intestinal obstruction operation will be lowered decidedly if we employ local anesthesia and not ether.

DR. C. N. COWDEN, Nashville, Tenn.: The pendulum is swinging the other way, and the surgeon who is not giving much study to local anesthesia at this time is missing a great opportunity of keeping himself abreast of the times. The post-operative effects of ether are to be remembered forever. It is practically accepted by every one that procain in large dosage is virtually free of toxic effect. One great difficulty is our lack of confidence in our ability to do these operations under local anesthesia. It is difficult to infiltrate a nerve, but we get practically the same effect by infiltration of the area through which the nerves pass. Gentleness in handling tissues, the sharp knife or scissors, lack of blunt dissection are factors which make for the success of operation under local anesthesia. Quinin and urea hydrochlorid has been responsible for some of the unpopularity of the local anesthesia operation, but the disastrous effect of that has now been banished. Operation under local anesthesia is one of the greatest advances made in the last year or two. The automatic injector adds greatly to the success of the method.

DR. J. A. RIVIER, Pittsburgh: Local anesthesia is the coming thing. I have been operating rather extensively under local anesthesia for about six years. Possibly the reason surgeons have failed to develop their local anesthesia technique is the fact that in a great many cases there is sloughing of the wound. Quinin and urea hydrochlorid is very bad for that. Procain alone will not give the desired anesthesia; it must be combined with epinephrin. In operating the field is dry; there is very little bleeding, and the operation is almost like a dissection on a fresh cadaver. By keeping the anesthetized area an inch or more away from the incision we can, in large measure, prevent sloughing or necrosis of tissue.

DR. A. C. SCOTT, Temple, Texas: When one undertakes to explore the abdomen under local anesthesia he can get just so far. The peritoneum cannot be anesthetized throughout. Although you may anesthetize the abdominal wall completely you will not be able to anesthetize the whole abdominal cavity. According to Dr. Farr you should depend more on visual

than on digital exploration. This is very good so far as it goes, but it seems to be a confession that the exploration cannot be made completely. I would not feel satisfied to close the abdomen without feeling the gallbladder, kidneys, pancreas and other viscera. You cannot make a satisfactory exploration of the abdomen without using the sense of touch. In anesthetizing the peritoneum near the abdominal incision, one of the best bits of technic is, as soon as a small opening is made through the peritoneum, to slip one finger on the inside of the peritoneum about 2 inches back from the margin of the wound and by placing the hypodermic needle directly through the rectus muscles the point of the needle touches the finger; the opening in the needle is exactly in the right position to infiltrate the subperitoneal tissue at the site of the most sensitive nerves. By doing that up and down both sides of the incision you secure the best sort of anesthesia of the abdominal peritoneum in the neighborhood of the wound. One part of abdominal work which cannot be done with local anesthesia without pain is in conditions in which you have to make traction on the mesentery. As soon as you pull on the meso-appendix in appendix operations, pain is produced. In ovarian cyst found during pregnancy, when you fear to give a general anesthetic we get magnificent results from local anesthesia. I have used it in diffuse peritonitis where the patient had double pneumonia and yet I did not dare let the peritonitis go without drainage and had equally good results. I have also used it in gastrectomy and conditions of that kind.

DR. ROBERT E. FARR, Minneapolis: I am not much of a golf player and do not believe in making all shots with one stick. However, when I do shoot I generally use my best stick. To my mind, the best stick in anesthesia up to date is local anesthesia, providing it can be used successfully. We see the same difficulty today with local anesthesia that we usually see when a man reads a paper on this subject. He is like the Christian scientists: he will not argue. These papers are discussed by local anesthesia enthusiasts who spend their time picking out a few of the known shortcomings of the method. Dr. Scott says: "You can not explore the abdomen." I say I can. If he cannot, I can not help that. Dr. Ruben says: "We have necrosis of the skin." I say we do not. We never have necrosis of the skin. If we keep the epinephrin below five drops to the ounce and put procain up in Ringer's solution, and make subdermal instead of intradermal infiltration, we do not have necrosis. Local anesthesia should not be blamed for the shortcomings of those who use it. I have been trying to make the use of local anesthesia simple. This can be done by the method I described and by the use of the apparatus shown. If by this method we can get anesthesia in approximately 100 per cent. of cases, why should we introduce double the amount of anesthetic surrounding the field of incision instead of infiltrating directly into it? Nerve blocking has its place and is an excellent method, but it requires an expert to spear for nerves, and this method will never become common. The method should be simple and easy for all to learn. I am not in sympathy with the idea of reserving local anesthesia for extreme cases. If this is a good thing for bad cases it should be a good thing for good cases. I believe that it is a good thing for all cases in which it can be used.

Virginia Antituberculosis Work.—The work is done county by county. One of the workers gets permission to appear before the council or board of supervisors, outlines the nature of the work and asks to be allowed to make certain investigations, saying that no obligation is attached to this, but that when the work is completed, certain reports and resolutions will be made which can be acted on at the discretion of the governing bodies. A few interested people are interviewed, the field nurse is introduced, and she does the rest, such as get in touch with families and with the doctors of the community, and offers her services for instructive care and bedside nursing when necessary. She will send patients to sanatoriums, arrange for free clinics, and health talks in the churches and at public meetings.—*Journal of Outdoor Life.*

STUDIES IN INFLUENZA AND PNEUMONIA

IV. FURTHER RESULTS OF PROPHYLACTIC INOCULATIONS *

E. C. ROSENOW, M.D.
AND
B. F. STURDIVANT, M.D.
ROCHESTER, MINN.

To determine the value of vaccination against disease, it is essential that the disease shall be one which a relatively large number of persons will develop unless protected, and that it be accompanied by serious consequences. These conditions were amply fulfilled during the pandemic of influenza. Moreover, the vaccine should contain the killed bacteria that produce symptoms and which are at least contributory to the cause of death. We have attempted, so far as possible, to fulfil this requirement by making a careful bacteriologic study of the disease, and by incorporating into the vaccine the important bacteria isolated. The epidemic was severe, and the need and the demand for vaccination were great; a large number of cases were available for bacteriologic study and to supply the proper strains for the vaccine. Vaccinations in large numbers during the past ten years with bacteria belonging to the group found in influenza have at least proved harmless, and in the case of pneumonia, prophylactic vaccinations have been successfully carried out by Wright,¹ Lister,² and Cecil and Austin.³ A splendid opportunity to study the effect of prophylactic inoculation was at hand. Owing to the foresight of the founders of the Mayo Foundation, necessary funds to meet the emergency were available. A large amount of the vaccine has been prepared and sent gratis on request to numerous physicians on condition that reports of the results be returned.

In a previous report,⁴ the reasons for the use of a mixed vaccine containing, as far as possible, freshly isolated strains were discussed. It was pointed out that the streptococci, especially green-producing streptococci from influenza, have certain peculiar properties. The preliminary results, as reported from the use of this vaccine, indicate that considerable protection is afforded against influenza and especially against the accompanying pneumonia. Vaccinations were begun soon after the onset of the epidemic. The period of observation was six weeks. It is our purpose in this paper to emphasize essential points in the preparation of the vaccine, to present further results from its use, and to record certain immunologic experiments.

COMPOSITION AND PREPARATION OF THE VACCINE

Influenza bacilli were isolated in large numbers at the outset of the epidemic, but they were rarely found later in the epidemic. The small fraction of influenza bacilli included in the first few batches of vaccine were therefore omitted, and the vaccine was made to contain a proportionately higher percentage of the green-producing streptococci. In other respects, the original formula has been adhered to. The formula as used in almost all cases covered by the present report is given in Table 1.

TABLE 1.—FORMULA OF VACCINE

Pneumococci, Types I (10 per cent.), II (14 per cent.), and III (6 per cent.)	30 per cent.
Pneumococci Group IV and the allied green-producing diplostreptococci described	40 per cent.
Hemolytic streptococci	20 per cent.
Staphylococci aureus	10 per cent.

The preparation of the medium, the method of cultivating and collecting the bacteria, and the procedure of standardizing the dose and killing the bacteria are described in the preliminary report.⁴ The vaccine, it will be remembered, was made to contain approximately 5 billion bacteria for 1 c.c. Later, the concentration was made twice as great, and the quantity of liquid was reduced to one-half. The injections were given subcutaneously one week apart. The first dose of the concentrated vaccine (0.25 c.c.) contained 2.5 billion, the second (0.5 c.c.) 5 billion, and the third (0.75 c.c.) 7.5 billion bacteria. Considering the large size of these doses and the reactions obtained, the injections should not be given oftener than once a week in order not to overstimulate the mechanism of immunity.

The tendency of streptococci to undergo changes and to lose specific properties has been repeatedly emphasized by one of us. It was thought important that freshly isolated strains should be included in the vaccine. In Table 2 are given the culture generations of all the strains that have been used throughout the epidemic. The fermentation power was tested of fifty-seven strains of the green-producing streptococci included in the vaccine; only twenty-seven fermented inulin, and only eight were bile soluble.

The advantages which should come from the use of a lipovaccine, particularly when a series of strains needs to be included, have already been pointed out.

and a simple method for the preparation in oil of a vaccine of the formula given in Table I has been developed and submitted for publication. A further study of the sputum and other material shows that of all the bacteria isolated, the somewhat peculiar green-producing streptococcus or diplostreptococcus is the most important. This organism is present in large numbers at the very outset of symptoms of influenza and of the accompanying pneumonia; it is commonly present after death. If the sputum or mass cultures are injected intraperitoneally into animals, they die, usually from invasion of the green-producing streptococci or pneumococci. If injected intratracheally in guinea-pigs the picture of influenzal pneumonia is closely simulated. Immunologic experiments with the serum from a horse injected with one strain indicate that most of the strains are immunologically alike. The serum of cases of influenza develops agglutinating power over these strains.

AGGLUTINATING POWER

In Table 3 it is shown that the vaccine used possessed well marked antigenic powers. The strains S 1, S 3, 2598², 2, 2604, 2, 3048, 3, and 2874² 3 were green-producing streptococci or pneumococci; 2575², 2, a hemolytic streptococcus, and 2608² 2, a staphylococcus from cases of influenza. It will be noted that agglutinins appear in the serum on the tenth day and persist for six weeks. Table 3 shows, moreover, that

TABLE 2.—CULTURE GENERATION OF BACTERIA FROM
INFLUENZA AS USED IN THE VACCINE

the bacteria in the vaccine (492) used as the antigen in the first column were susceptible to agglutination. This vaccine was prepared three months previously and was kept in the ice chest. Most of the strains used as antigen in the experiment recorded in this table were not included in the vaccine used to immunize the persons whose serums were tested. All the green-producing streptococci were agglutinated, however, by the monovalent horse serum.

TABLE 3.—AGGLUTINATING POWER OF THE SERUM OF PERSONS INOCULATED WITH SALINE VACCINE

[illegible]

In Table 4 are given the results following the injection of a single dose of the lipovaccine (from 25 to 75 billions) in three persons. It may be noted that the amount of agglutination is greater than that following the injection of the saline vaccine, but here, as in the case following the injection of the saline vaccine, not all strains are equally susceptible to agglutination, and some are not agglutinated at all.

Table 5 shows the agglutinating power of various immune horse serums over strains of green-producing streptococci from influenza, strains included in the vaccine. The serum from Horse 15, immunized with one strain from the blood of a patient who died, has marked agglutinating power over most of the strains. Of the thirty-three strains tested in this manner, twenty-five were agglutinated specifically by this serum. The results indicate clearly that among the green-producing streptococci, including Group IV pneumococci in influenza, there are strains which have a specific

reacted severely to all three inoculations, others only to one or two. Persons coming down with a cold or with symptoms of influenza are often hypersensitive. Marked diffuse redness resembling erysipelas about the site of inoculation, with swelling and, later, marked induration, has occurred occasionally. In no instance were the symptoms alarming. The number of severe reactions is sufficiently large, however, to prevent general vaccination except at the time of an acute emergency. This is in accord with the experience of Cecil and Austin,³ noted during prophylactic inoculations with pneumococci. An outline for records of persons vaccinated was sent with each batch of vaccine and later a questionnaire. The questionnaire asked for the date of the onset of the epidemic, the date when the vaccine was first used, the week of the height of the epidemic, the week in which the greatest number of vaccinations were given, and the duration of the epidemic. The number of cases of influenza from the time the vaccinations were begun until the end of the epidemic, or up to May 1, and the number of deaths which occurred among the vaccinated and unvaccinated in the same period, in the practices of the physicians supplied with the vaccine, were asked. The reports of the use of the vaccine after the epidemic had disappeared were excluded. The period of observation in most instances was from four to five months.

In determining a safe criterion as to the value of the vaccine, we have purposely been unfair to the vaccinated group. The protection afforded among the vaccinated patients was measured from the day of the first vaccination, whereas, judging by the agglutination experiments, it should be calculated from about one week after the third injection.

There is another reason why we have arbitrarily decided to make our calculations from the day of the first vaccination. A procedure, calculated to protect against an epidemic disease, such as influenza, should

relationship, and that we were fortunate in successfully separating them from the ordinary *Streptococcus viridans* and including them in the vaccine long before the results of immunologic experiments were available.

The apparent protection against attacks of influenza noted in the preliminary report, difficult to understand at that time, now becomes rational.

METHOD OF SECURING DATA

In most instances the reactions were mild, about one person in each 100 reacted more severely. Some

have sufficient protective value when given after the onset of the epidemic to be measurable, for it is practically impossible to anticipate these epidemics and, moreover, persons will not present themselves for vaccination until the epidemic is at hand.

The questionnaire was arranged so as to yield information regarding the incidence of influenza, acute edema of the lungs, pneumonia and empyema, and the deaths from acute edema of the lungs, pneumonia, empyema, meningitis, and encephalitis among the vaccinated and the unvaccinated. Separate reports includ-

ing the foregoing points were asked for from institutions and in the cases of pregnant women. The impressions gained from the use of the vaccine regarding the severity of the disease if contracted following vaccination, and the effect, if any, which the vaccine had on certain chronic infections, such as bronchitis, sinusitis, myositis, and arthritis were asked for.

Many physicians were so overwhelmed during the height of the epidemic that accurate records could not be kept, and accordingly the reports containing accurate data are proportionately few. The reports of 530 physicians were fairly complete, however, and these are summarized in Table 6. It is realized that there must necessarily be errors in the morbidity figures as reported to us, just as in the case of reports to boards of health. It is generally agreed that as influenza became more prevalent and less severe, a proportionately smaller number of cases were reported, and that all morbidity figures reported are well below the actual figures. The error, however, among the vaccinated and unvaccinated groups in the reports to us, should be approximately the same, and hence the figures should be comparable. Mortality figures, on the other hand, may be considered as fairly accurate.

mer in these three decades were 23, 19, and 21, of the latter 13, 29, and 23, respectively. Through the cooperation of the Board of Health of Minnesota we were able to check the results as reported to us with the morbidity and mortality figures as reported to them. Reports on a considerable number of vaccinations were received from Brown, Chippewa, Clay, Dodge, Fillmore, Goodhue, Houston, Itasca, Lesueur, Lyon, Mower, Olmsted, Rice, Stearns, Steele, Wabasha, Waseca, Watonwan, and Winona counties. The total estimated population of these counties is 472,584. The total number of cases of influenza in these counties reported to the board of health from the beginning of the epidemic until May 1 is 30,763, or sixty-five for each thousand. This is admittedly a low figure. The total mortality rate as reported to the board of health during this time is 4.2. The mortality rate, excluding the deaths which occurred in the respective counties prior to the date of the first vaccinations, is 3.2 (Table 7). The figures in the table indicating the cases and the deaths as reported to us are believed to be more accurate. The mortality rate, exclusive of that of the Mayo Clinic, in the 17,532 persons vaccinated three times is only one fourth of that reported to the

RESULTS OF INOCULATION

The total number of unvaccinated persons recorded in Table 6 represents the sum of the estimated clientele of the various physicians reporting the cases, and averages about 1,200 for each. It will be noted that the incidence of influenza, of acute edema of the lungs, of pneumonia following influenza, and the number of deaths from all causes among the vaccinated are consistently lower than that among the unvaccinated. Moreover, the incidence of disease and deaths is lowest in the group of 93,476 persons who were vaccinated three times. The reports included in this table were from many states, but the largest number came from Iowa, Minnesota, and Wisconsin. Thirteen thousand, six hundred and fifty persons inoculated and 2,083 who died were grouped according to age by decades. The curves indicating the percentage in each run roughly parallel.

The largest number of inoculations were given and the largest number of deaths occurred between the ages of 11 and 40 years. The percentages of the for-

board of health. Moreover, the total number of deaths among the vaccinated, including the persons inoculated only once and twice, is 1.6 for 1,000, or half the mortality rate as reported to the board of health during the same period of time. When we consider the fact that the deaths in each group were counted from the time the first vaccinations were given, which is really unfair to the vaccine, and the fact that our figures include all pneumonias, while those of the board of health include only the influenzal pneumonias, there seems little doubt that the difference must be due to the protection afforded by the vaccine. The figures given in Table 8 for Olmsted County, where about one third of the population was vaccinated, exclusive of the Mayo Clinic and the state hospital, are similar to those obtained elsewhere. The incidence of disease and the death rate among those vaccinated three times are well below that of those not vaccinated.

The results obtained in institutions in which the conditions among the vaccinated and the unvaccinated

were comparable are summarized and given in Table 9 in order still further to check the figures. The number of persons in most of the institutions included (fifty-three in all) was small. The opportunity for accurate observation was, therefore, favorable. The institutions included factories, personnel of hospitals, schools, and offices. The proportion of the vaccinated and unvaccinated varied between wide limits. The period of observation in the two groups was the same. The

TABLE 9.—RESULTS OF PROPHYLACTIC INOCULATION IN INSTITUTIONS WHERE THE CONDITIONS AMONG THE VACCINATED AND UNVACCINATED WERE COMPARABLE

Groups	Total Number	Incidence for 1,000 Persons—Disease					Deaths—	
		Influenza	Acute Edema of Lungs	Pneumonia	Empyema	Acute Edema of Lungs	Pneumonia	
Vaccinated 3 times	5,296	21	0.1	1.0	0.2	0	0	0.5
Not vaccinated....	9,288	290	0.5	12.0	0.6	0.4	0.5	5.5

incidence of disease and the number of deaths in almost all instances were lower in the vaccinated than in the unvaccinated group. The total average, as given in Table 9, compares favorably with that of the others. The death rate among the vaccinated is decidedly lower than among the unvaccinated.

The results given in the tables are in agreement with the numerous reports received by which it appeared that the vaccine had afforded striking instances of pro-

tection. In a few cases no protection seemed to be afforded, but in most of these the vaccinated persons contracted the disease a long time after the inoculations. It is fully realized how difficult it is to judge just how much protection was conferred in many of these instances, and how much of the apparent protection was merely coincidental. But a careful study of the reports from 303 physicians, some of which were the result of careful observation, forces the conviction that real protection, especially against pneumonia, was afforded. In some of these instances most of the observations were made within six weeks to two months after the vaccine was given.

It was thought that the injection of large doses of a mixed vaccine might have some effect on certain chronic infections, especially of the respiratory tract. A summary of the reports shows that 961 persons with chronic bronchitis were benefited and that thirty-eight were made worse. The reports show that 127 persons with chronic sinusitis were benefited and four made worse. Improvement was noted in 121 persons having myositis and in 129 with arthritis, while in one of the former and in twenty-two of the latter the symptoms were aggravated. These figures are not considered to be especially significant but worthy of record. They are in accord with our own observations.

10. The incidence of disease and that of miscarriages and the mortality rate are consistently lower among those vaccinated than among those not vaccinated. The mortality (20 per cent.) of the unvaccinated pregnant women who developed influenza is somewhat lower than that reported from similar statistical studies by Bland⁵ and by Harris.⁶ They report a mortality of 37.7 per cent. and 27 per cent., respectively. The mortality of 12 per cent. in the 997 pregnant women inoculated in our series is in sharp contrast and calls for a further trial of this measure.

Almost from the beginning of the epidemic of influenza, patients who registered at the Mayo Clinic were advised to be vaccinated. From October 1 to May 1, 55,189 patients registered. Of these, 2,542 were vaccinated once, 1,030 twice, and 1,850 three times, a total of 5,422. A reliable morbidity and mortality rate for each thousand of the vaccinated and unvaccinated could not be determined because such a large percentage of patients remained in Rochester for too short a time.

It was thought that a study of the cases of influenza admitted to the hospitals might, however, be worth while. Of these, 740 were undoubted cases of influenza, and were analyzed from various standpoints. Fifty-nine of the patients were vaccinated once; twenty-four, twice, and fifty-seven, three times, while 609 were not vaccinated. The incidence of pneumonia and the deaths from pneumonia in these groups are

TABLE 10.—RESULTS OF PROPHYLACTIC INOCULATION IN PREGNANCY

Groups	Total Number	Incidence for 1,000 Persons—Disease					Deaths—			Mortality of Those Who Developed Influenza
		Influenza	Acute Edema of Lungs	Pneumonia	Empyema	Miscarriage	Acute Edema of Lungs	Pneumonia	Menigitis	Total Deaths
Vaccinated 3 times	997	109.3	17.0	27.0	14.0	2.0	12.0	14.0
Not vaccinated....	3,656	291.6	17.7	89.4	0.82	16.2	12.3	46.2	0.54	59.9

recorded in Table 11. The average interval between the vaccinations and the onset of influenza was nine days in those vaccinated only once, twenty-six days in those vaccinated twice, and forty-five days in those vaccinated three times. The average temperature was more than one degree higher in the unvaccinated than in the vaccinated, and the average duration of fever nearly two days longer. The percentage incidence of pneumonia in those vaccinated three times was 21; in those not vaccinated, 57, while the percentage of deaths

TABLE 11.—RESULTS IN CASES OF INFLUENZA ADMITTED TO HOSPITALS IN ROCHESTER

Groups	Cases of Influenza	Incidence of Pneumonia	Deaths from Pneumonia, per Cent.
Vaccinated once.....	50	30	10
Vaccinated twice.....	21	30	12
Vaccinated three times.....	57	21	5
Not vaccinated.....	609	57	22

from pneumonia was 5 in the former group and 22 in the latter. The mortality from pneumonia of those vaccinated only once and those vaccinated twice is also well below that of the unvaccinated. The mortality figure in the unvaccinated is abnormally high because only the patients with relatively severe attacks were admitted to the hospitals.

RESULTS OF PROPHYLACTIC INOCULATION IN PREGNANCY

The results of vaccinations in pregnant women as reported in the questionnaires are summarized in Table

⁵ Bland, P. B.: *Influenza in Its Relation to Pregnancy and Labor*, Am. J. Obst., 79: 184-197 (Feb. 1919).

⁶ Harris, J. W.: *Influenza Occurring in Pregnant Women*, J. A. M. A. 72: 978-980 (April 5) 1919.

The greater tendency to the development of pneumonia in influenza among the unvaccinated group as observed in this series is in keeping with the lower incidence of this complication (4.7 per cent.) in 11,325 cases of influenza in which the vaccine was given after the onset of the symptoms, as compared with the incidence (8.7 per cent.) in 41,788 cases in which the vaccine was not used. The average mortality in the cases in which the vaccine was used in treatment was 1.4 per cent.; in those not treated it was 2.1 per cent.

From these results considerable weight may be attached to the opinion of nearly all the 430 physicians who have used the vaccine and who have reported on this point, an opinion in agreement with our own observations, that is, that the attacks of influenza if contracted following vaccination are milder and of shorter duration.

SUMMARY

The immunologic and animal experiments reported⁷ elsewhere indicate that the mixed vaccine used by us contained the important bacteria as they occur in influenza and the accompanying pneumonia, and that a relatively large number of strains of the green-producing streptococci which appear to have a specific relationship to the initial attack were included. The reports included results obtained under the most varied conditions, from many communities covering a wide range of territory. In some communities the mortality rate was excessively high, in others comparatively low. The number of persons inoculated is sufficiently large to make the statistical figures fairly accurate. The period of observation was from three to seven months. The incidence of influenza and pneumonia as reported to us is probably far from exact, but the percentage of error should be about the same in the vaccinated and unvaccinated groups. Indeed, if a difference exists, the number of cases reported among the vaccinated might be expected to be proportionately higher because, even though no protection was promised, the fact that influenza occurred after the vaccinations were taken would naturally lead to a higher percentage of reports to the physician who gave the inoculations. The average incidence of influenza and pneumonia in the group inoculated three times is about one-third that of the uninoculated group.

The average mortality rate in the uninoculated, as reported to us, approximates the mortality rate (5.4 per cent.) of sixteen large cities of the United States as given in *Public Health Reports* for February 7. The average mortality rate in the group inoculated three times is about one-fifth that of the uninoculated. A definite although a smaller degree of protection appeared to be afforded to those who took only one or two inoculations. From a study of a series of hospital cases of influenza it is found that the tendency to the development of pneumonia in the vaccinated is about one third as great as among the unvaccinated, and that the mortality in the former is about one fifth as great as in the latter. The number of completed vaccinations in pregnant women is not large enough to give exact figures, but the results indicate clearly that a definite degree of protection was afforded in this group of individuals.

It appears from all the facts at hand that by the use of a properly prepared vaccine it is possible to rob influenza of some of its terrors.

The preliminary results from the use of more than 500 doses of this vaccine suspended in oil, the immunologic studies and the results from the use of pneumococcus lipovaccine reported by Fennel⁸ and by Cecil and Vaughan⁹ suggest strongly that both the degree of protection and the duration of the immunity may be materially increased by the use of lipovaccine over that reported in this paper from the use of the saline vaccine.

STATUS OF PROPHYLACTIC VACCINATION AGAINST INFLUENZA *

G. W. MCCOY, M.D.

Director, Hygienic Laboratory, U. S. Public Health Service
WASHINGTON, D. C.

When we consider the tragic experience through which the country and, indeed, the world, has passed during the last year, we realize that a great advance in preventive medicine would be made by the discovery of a prophylactic agent which would enable health authorities to control effectively epidemic influenza or the pneumonia that so often occurs as a complication. Perhaps at the outset it may be profitable to take stock of what we know about the etiology of influenza and the etiology and pathology of influenzal pneumonias.

OPINIONS AS TO ETIOLOGY OF INFLUENZA AND INFLUENZAL PNEUMONIA

Though the organism described by Pfeiffer in 1891 has long been known as the influenza bacillus, there really never has been convincing evidence of its relation to influenza, and the data that accumulated during the epidemic or epidemics here and abroad this past year have not contributed any confirmation to the view that this germ is the cause of the disease.

In this connection it should be borne in mind that it is quite possible that there are a number of organisms, varying greatly in pathogenicity, which are grouped under the name of Pfeiffer's bacillus. We have only to recall the great differences that exist in other groups, in which organisms having common cultural and morphological characteristics vary greatly in disease-producing properties, to realize that the rather vague limitations of what is called the influenza bacillus may cover a number of more or less closely related organisms.

French and English workers have claimed to have produced influenza by means of a filterable virus; this would, indeed, definitely eliminate Pfeiffer's bacillus; but we must bear in mind that attempts to produce the disease in man artificially in this country, by means of both filtered and unfiltered secretions, have in practically every instance been negative. Similar attempts by means of cultures of the so-called influenza bacillus have been negative.

A.* 72:1604-1608 (May 31) 1919. The Occurrence of a Pandemic Strain of Streptococcus During the Pandemic of Influenza, Study III, *ibid.* pp. 1698-1699.

When we turn to the views on the etiology and pathology of influenzal pneumonia, we find a rather general opinion that the pneumonia is due to Pfeiffer's bacillus or to the secondary invasion by organisms of acknowledged pathogenicity, particularly the various types of pneumococci, the streptococci, especially those known as hemolytic, and, less commonly, Friedländer's pneumobacillus or the staphylococcus.

A few observers are inclined to the opinion that the original cause of the influenza, be it the influenza bacillus or another organism, is also an essential factor in the production of the pneumonia. This view would appear to be entitled to much respect, on account of the rather general opinion among pathologists that the pneumonia following influenza is generally of a type distinct from the pneumonias ordinarily encountered.

A number of interesting papers have appeared on the pathology of influenzal pneumonia, and a complete review of them would be valuable; but, for the present purpose, we may say that, in general, the pneumonias do not conform to those due to the organisms which are usually associated with pneumonia. Lack of definite areas of consolidation, the absence of the usual fibrinous pleural exudate, the extreme wetness of the lungs, and the blood-stained pleural fluid usually found bilaterally, in most cases serve to differentiate influenzal pneumonias from those ordinarily due to pneumococci, as lobar pneumonia. Emphasis is laid on this point because some workers have hoped that immunization against lobar pneumonia, which appears to be practicable, might prove of great value against influenzal pneumonia; but if the lung lesions of the two diseases are so different, one suspects there may be a material difference in etiology, and that this difference may be of such a nature as to make what appears to be a valuable prophylactic agent in one case of no use in the other.

Rosenow¹ calls especial attention to the fact that "the findings in the lungs, for example, in the so-called acute bronchopneumonia following influenza, are quite unique and are strikingly similar, irrespective of the species of microorganism present." This is quoted to emphasize the point that it is entirely possible that all of these lesions may be due to the primary cause of influenza, and that the various organisms which have been recognized in various cases and various places may really not reach even the dignity of secondary invaders, but may be looked on as leading a relatively saprophytic existence in the tissue damaged by the primary cause of influenza, whatever that may be. With this brief preliminary consideration of these important matters, let us consider the experience with prophylactic vaccination.

VACCINE FROM INFLUENZA BACILLUS AS A PROPHYLACTIC

In discussing this subject, we will give attention, first, to the results obtained from the use of a vaccine made from the influenza bacillus alone, or from other suspected etiologic agent, which aims, to be sure, to prevent the primary disease, and later to a review of the evidence with respect to vaccines which have been devised with the special object of preventing the development of pneumonia or of mitigating its severity.

A vaccine made from the influenza bacillus alone seems not to have appeared sufficiently to European

workers to induce them to try it when the epidemic prevailed abroad. In this country, its use has been confined largely to New England. The early reports on this vaccine were very encouraging; figures were presented which, if taken at their face value, would convince any one of the efficiency of the agent; but, when these figures were submitted to careful analysis, much doubt remained as to whether the vaccine was of any service whatsoever. The chief source of error lay in the fact that the inoculations had been done during the progress of the epidemic, and that the case incidence among the vaccinated was compared with the case incidence in the general population or in the control groups from the beginning of the epidemic. Now, it is plain that if, after the epidemic is well under way, we vaccinate a portion of the persons in a population, the percentage of persons attacked will be smaller among the vaccinated than among the non-vaccinated, because a percentage of the total number of cases will have occurred before the vaccine is given. Not only does this introduce an error by counting in the control, or nonvaccinated group, cases that have occurred early, but also it leaves a select group to be vaccinated, wholly or in part, in which the percentage of susceptibles is smaller than in the original group of which they formed a part.

To make this clear, let us suppose that ten days after an epidemic started in a population of 1,000 persons, an admittedly worthless vaccine was administered to one half of those who at that time remained unattacked by the disease. Let us further assume that on the date of vaccination 20 per cent. of the population had sickened, leaving 800 well persons, of whom 400 were vaccinated. Since the hypothetical vaccine is worthless, the morbidity will be as great in the vaccinated as in the nonvaccinated group. Let us assume this to be an additional 20 per cent. Then the total morbidity in the vaccinated group will be 20 per cent. of 400, or eighty cases. The total morbidity in the unvaccinated, however, if we consider the entire period of the epidemic will be 20 per cent. of 1,000, or 200, plus 20 per cent. of 400, or eighty, which would make 280 cases.

Although the error is now sufficiently clear, we have seen reports which, on the basis of the above figures, if applied to this hypothetical worthless vaccine, make it appear to be a valuable prophylactic. The statement of these reports would be, in effect, that one half of the population was vaccinated, that among the vaccinated only eighty cases developed, while among the unvaccinated 280 cases appeared. Hence the obvious value of the vaccine.

We must also remember that a vaccine can scarcely be expected to exert any appreciable prophylactic effect before from seven to ten days after the vaccine is given, since a week or more is required for immunity to develop. A comparison is fair which considers, among both vaccinated and nonvaccinated, only cases that have occurred, say, ten days or more after the vaccinations are made.

When the influenza bacillus vaccine was submitted to such critical tests as the inoculation of approximately half of the individuals in institutions, or in other large groups, its failure became apparent. A few examples of this are worth citing. Hinton and Kane² were able to vaccinate about half of the patients at an epileptic

2. The Commotow alb., *Monthly Bulletin, Massachusetts State Department of Health*, 6:28, Nos. 1 and 2, 1919.

colony long enough before the disease became prevalent in the institution to justify the drawing of conclusions from their data. The vaccine used contained 800,000,000 organisms per mil, and a total of 2,000,000,000 were administered to each person. The results were as shown in Table 1.

TABLE 1.—EFFECT OF INFLUENZA BACILLUS VACCINE AS A PROPHYLACTIC

	Vaccinated		Not Vaccinated (Controls)	
	No.	Per Cent.	No.	Per Cent.
Number of persons	461	...	518	...
Cases of influenza	163	35.4	178	34.3
Deaths	28	17.0	24	13.5

On the basis of this experiment the authors reach the obvious conclusion that the vaccine was without value.

A similar test was made on the naval personnel at Pelham Bay Training Station; here a part of the individuals of a group were vaccinated, the remainder being held as controls. According to the latest available report,³ 9 per cent. of the 554 inoculated persons developed the disease, and 5 per cent. of the 800 who had not been inoculated developed it.

Similar failure attended the attempts at immunization of men at the naval base at Paris Island, S. C. It was definitely shown that neither incidence nor severity was influenced by the vaccination. These observations were all on groups large enough to make the deductions of value.

A number of controlled vaccinations, in which influenza bacillus vaccine was used, carried out in institutions by the Public Health Service, gave the rather paradoxical result of showing an increased percentage of attacks among the vaccinated, but more deaths among the nonvaccinated. This result was obtained with a vaccine directed against the primary disease, not against the complicating pneumonia. The results are shown in Table 2. These figures illustrate the fallacy of giving much weight to the results of a small set of observations in work of this sort.

TABLE 2.—RESULTS OBTAINED BY INFLUENZA BACILLUS VACCINE IN INSTITUTIONS

VACCINES FROM STREPTOCOCCUS AND OTHER ORGANISMS

Another series of vaccinations aimed directly against the supposed causative agent was that reported by Ely, Lloyd, Hitchcock and Nickson.⁴ These workers believed that the epidemic was due primarily to a hemolytic streptococcus which could be detected in the blood and in the lungs. From the fact that the organisms with which these observers worked soon lost their chain-forming properties and, in some instances, the power to hemolyze promptly, they express some doubt as to whether they should be classed as streptococci, and they further assume that there are material differences between different strains. The results of the use of a vaccine prepared from organisms isolated from the cases were apparently most

encouraging, though none of the experiments was controlled in a manner that would definitely establish the value of the preparation. The work of these observers needs to be repeated before the results can be accepted for general application.

When we come to consider the evidence with respect to the vaccines especially designed to prevent the pneumonic complications of influenza, we find again such conflicting reports that one is somewhat bewildered.

The only papers from a foreign source that have come to my notice are those by Eyre and Lowe,⁵ who used a mixed vaccine which contained the pneumococcus, the streptococcus, the influenza bacillus, *Staphylococcus aureus*, *Micrococcus catarrhalis*, *B. pneumoniae* and *B. septus*.

These authors believe, and indeed present rather convincing figures in their first paper⁵ to prove their point, that the use of this vaccine produces lowered resistance, which may last for "from a few hours to two or three weeks," during which period the incidence of respiratory infections would be increased among inoculated groups.

The early experience of the English authors does not refer directly to the prophylaxis of influenza, but it is cited here to show that there may be an element of danger in the indiscriminate use of vaccines in the presence of a rapidly spreading epidemic like influenza in which naturally many persons in the "negative phase" would be attacked.

In a later paper,⁶ the same writers report on the experience with vaccine in the epidemic in England in the autumn of 1918. Stress is laid on the necessity of preparing a vaccine from cultures but recently isolated.

The figures given and the facts presented by these writers are difficult of interpretation and permit of almost any conclusion that one wishes to draw from them, from the optimistic one that fatalities after influenza occur only among the nonvaccinated, to the pessimistic one that fatalities occur only among the vaccinated, though the authors believe the results were good. They frankly reiterate the opinion that for a short time following vaccination there is an increased incidence among the vaccinated, owing to temporarily increased susceptibility, but the writers consider that this risk is justified by the benefit that they believe may accrue later. As inoculations were performed largely during the prevalence of the epidemic, and as the controls appear to include persons who developed the disease prior to the vaccination, the alleged good results may be misleading.

THE POLYVALENT VACCINE OF ROSENOW

Rosenow⁷ prepared a mixed, and, at least in part, polyvalent, vaccine from the various fixed types of pneumococci, pneumococci of Group IV, hemolytic streptococci, *Staphylococcus aureus* and the influenza bacillus, all of which had been recently isolated. This vaccine was adjusted to meet the bacterial flora encountered during the epidemic; thus, in a manner it may be said that it was designed to approach an autogenous vaccine, but was intended primarily for prophylactic purposes. Dr. Rosenow felt that this vaccine should be prepared for use in any community from the strains of organisms there prevailing, and that a vaccine adjusted to meet the needs of one local-

3. Notes on Preventive Medicine for Medical Officers, U. S. Navy bulletins, Nos. 50 and 51.

4. Ely, C. E.; Lloyd, B. J.; Hitchcock, C. D., and Nickson, D. H.: Influenza as Seen at the Puget Sound Navy Yard, J. A. M. A. 72:24 (Jan. 4) 1919.

5. Eyre and Lowe: Lancet 1923:484-487.

6. Eyre and Lowe: Lancet 1916:753-760.

ity might not meet those of another. The figures given for protection are encouraging, but do not lend themselves to critical analysis.

Dr. Rosenow considers the immunity produced by his vaccine to be of relatively slight duration, as some persons were apparently protected during the first wave of the epidemic, but not during the second.

A vaccine, prepared essentially in accordance with Dr. Rosenow's formula, was used extensively in the Middle West with alleged good results, but it was not used until the epidemic was at, or beyond, the crest, and the records are not convincing. Vaccine prepared in the manner suggested by Dr. Rosenow should theoretically have a better chance for success than those we shall next consider, but the practical difficulties of preparing it from locally prevailing strains and adjusting it to meet the changing flora of the respiratory tract in a disease that spreads as rapidly as influenza are obvious.

A specimen of the vaccine which was being used in Illinois was tried in California, under rigidly controlled conditions, without success. The disease did not appear in the institution where the test was made until eleven days after the last injection, but, after the epidemic had swept through it, the results revealed that 37 per cent. of the vaccinated were attacked, against 28 per cent. of the controls, while 4.5 per cent. of the vaccinated population died, against 3.6 per cent. of the nonvaccinated. These are differences too small to be significant. Tests made in other institutions gave similar results, though we need not take the time to consider the details here.

There are several other reports of the use of vaccines prepared somewhat along the lines of Dr. Rosenow's, but the data are not presented in a manner to permit of analysis.

The only report we have on a vaccine directed against the influenzal pneumonias associated with the fixed types of the pneumococcus is that of Cecil and Vaughan,⁷ whose work was conducted at Camp Wheeler and was directed primarily against the usual pneumonias of the camp. Apparently the antipneumococcus vaccine reduced somewhat the incidence of influenzal pneumonia among the vaccinated, though, to use the author's words, "influenza causes a marked reduction in resistance to pneumonia even among vaccinated men." These authors show clearly that the case mortality of secondary pneumonias was not reduced by the vaccination, contrary to the claim so often made, that the vaccine, when it fails to protect perfectly, at least leads to a milder type of the disease. Cecil and Vaughan believe that the results of their experiment with respect to pneumococcus pneumonia were obscured by the influenza epidemic; evidence that the prophylactic action of the vaccine employed against influenza was not striking, since the epidemic should have served to emphasize rather than obscure the results of the beneficial action of a really valuable prophylactic agent.

We must next consider, briefly, the stock commercial vaccines made from about the same organisms that went into the vaccine prepared by Dr. Rosenow. Concerning these there are no accurate figures. So far as I have been able to determine, the preparations have not been used anywhere under properly controlled conditions. What we have to consider are, chiefly, the enthusiastic reports of observers whose faith was bet-

ter developed than their judgment. A strenuous effort was made to secure the endorsement of the federal government for this form of prophylaxis against influenza. Under the direction of the Surgeon-General of the Public Health Service, careful investigators were sent to several communities from which glowing reports were received regarding the great value of stock vaccines, but in no case could the claims be verified. In this connection, we may trace the waning enthusiasm of one man who early in the epidemic reported that "immunization, using mixed vaccines, has proved beyond any question of doubt to be of great prophylactic value . . . why not extend this to all the people?" Ten days later, this man advised us that "we felt there was a strong possibility of it [the vaccine] preventing many cases. . . . At the present time we are not in a position to make any absolute and definite statement." So far as we know, the final reports from this source never have been published, though ample time has elapsed.

People wondered that those in positions of responsibility did not accept the first enthusiastic reports, adopt an attitude of optimism, and recommend the universal use of vaccination against influenza; but, in the light of present knowledge, there seems to have been some justification for an attitude of conservatism.

It must be clearly understood that what has been said above does not apply to vaccination against lobar pneumonia, using pneumococcus vaccine. The evidence on this is favorable, though perhaps the final word has not yet been said. It may be noted here that the very optimistic reports by Lister, who introduced vaccination against lobar pneumonia, are being called into question.⁸ The rather startling suggestion is made by Fennel⁹ that this antipneumococcus vaccine may be useful in combating epidemic influenza, but he admits the "information at hand is fragmentary and not to be seriously considered though possibly significant."

Though the evidence in respect to any vaccine that has been tried offers little to warrant hope that an effective agent has been found, we must not feel unduly pessimistic. The problem of vaccination in influenza is an extraordinarily difficult one. The etiology is uncertain, the influenza bacillus and the streptococci are poor antigens, and the epidemics are so far apart and so rapid in passage that the time to work out a prophylactic agent is very limited.

CONCLUSION

The general impression gained from uncontrolled use of vaccines is that they are of value in the prevention of influenza; but, in every case in which vaccines have been tried under perfectly controlled conditions, they have failed to influence in a definite manner either the morbidity or the mortality.

Making a Skilled Physician.—Hippocrates named six conditions necessary to become a skilled physician: Natural talent, instruction by a competent master, a place favorable to study, education begun in youth, love of work and long application. The first of these conditions is the most important, for where there is not a natural disposition it is useless to attempt to force Nature. Theory should be combined with practice. Want of experience begets either timidity or rashness. Timidity discloses impotence and rashness ignorance. Tweedy, *Brit. M. J.* 2:598 (May 17), 1919.

GASTRIC CELL PRIMARY ATROPHY*

ANTHONY BASSLER, M.D.

Professor of Gastro-Enterology, Fordham University School of Medicine and New York Polyclinic Medical School and Hospital

NEW YORK

Achylic conditions of the stomach may be divided into: (1) those in which it seems to be normal in the individual, has always been and will be present throughout the life of the person, and in whom it has not and most probably will not affect the general state of health or ever cause local symptoms; (2) the psychologic cases, such as fear of the passage of a stomach tube, or the effect of depressing emotions (worry, grief, anxiety, suspense); (3) reduced state of general body from fevers and senile conditions; (4) endocrinitic or hormone disturbances, of which we know little, and (5) pathologic conditions of the stomach glandularis in which the secreting ability is destroyed by disease of the essential elements, namely, the acid and central cells.

To the latter, the term atrophic gastritis should be given, a far better term for it than to designate it as achylia gastrica, because it expresses pathology instead of only a symptom. In no entity of medicine are more mistakes made than in instances of atrophic gastritis, when they are called achylia gastrica. The latter term should be confined to the normal nonacid stomachs, which, for some reason, have acquired symptoms, to the psychologic endocrine, the general vitality reduction and the senile cases. In my opinion, almost every instance of so-called gastrogenic diarrhea with persistent achylia, whether increased amounts of mucus are present in the stomach or not, should be viewed most probably as an atrophic gastritis. Expressions in terms of symptoms may be satisfactory to some, but they do not meet one of the cardinal commandments of scientific medicine as do expressions in terms of pathology.

Pathologic studies of the stomach glandularis on the cadaver and such specimens as were obtainable at operation were made to study gastric cells. The observations were that in the atrophic and hypertrophic types of chronic gastritis there is generally presented in the glandulature the characteristic picture of a cell atrophy, but this comes very probably in a secondary way from interference with the nutrition of the cell, due to contraction of fibrous tissue, low intratubular and subatubular in location. In primary cell change the atrophy seems to begin as a process in the cell protoplasm, and is apparently not secondary to change in the basement membrane, nor is there accompanying it any significant round cell infiltration or organization of fibrous tissue. The fibrous tissue formation may be and often is met with; but then it is present as an entity making up a chronic gastritis. The commonest and the most perfect instances of cell atrophy come and develop without any evidence of chronic inflammation, and are represented in a granular degeneration of the cell body and desquamation which goes on until the cells disappear. Whatever the degree met with, the process is general throughout the entire organ, although in the pyloric region the so-called pyloric glands usually

escape. Thus it is apparent that the old designations of atrophic gastritis should be retained; but as a designation it should be confined to the late stage of chronic gastritis in which round cell and fibrous tissue infiltration and others are primary factors, and then there is reason to consider it as a form of stomach disorder, a granular protoplasmic degeneration, which really is not a true gastritis at all.

Work was done if possible to elucidate a factor or factors in the production of this condition. For the purpose, fourteen cadavers in which this stomach condition was found to be present were carefully studied. These were all instances of death from chronic infections: Eight were instances of tuberculosis in which mixed infection existed. Two were instances of chronic septic conditions of the gallbladder resulting in rupture and general peritonitis. One was a gram-positive diplococcus systemic infection following four years after a pneumonia in which a large abdominal abscess occurred. Another was meningitis following long standing ethmoidal disease. Still another was systemic infection following a pylonephritis of three years' standing, and the last, a suppurative endocarditis of low degree.

In addition to these, there were nine instances of operations on chronic septic conditions in which pieces of stomach glandularis were obtained for section. They comprised four instances of subacute suppurative cholecystitis, three instances of long standing appendicular disease with mass adhesions, a suppu-

tive Meckel's diverticulum, and a perforated gastric ulcer with local abscess formation and a chronic sinus between the abscess sac and stomach cavity.

As a result of these studies it was suggested that in infections of long enough standing in the body, a degeneration of gastric secreting cells could occur either from toxic effects from the bacteria affecting the cell protoplasm from the systemic side, the stomach acting as an excretory organ to those toxins, or that because infective organisms were found in the stomach tissues in all cases but one, free in very increasing numbers in the stomach cavity and outside the stomach, this stomach condition was directly bacterial in origin.

From this point, the studies were changed to routine clinical cases. In all the anachlorhydric cases seen, care was exercised to eliminate the congenital, psychologic, the conditions in persons who had recently recovered from marked acute infections, and the senile. Also thrown out were instances of chronic alcoholism, cases in which we could feel that the anachlorhydric condition might have been due to dietetic errors, and those in which the condition could be ascribed to local causes in which a chronic gastritis was probably present. There were many instances by the most careful analyses of which we could not be definite as to classification that were not included. Each case was examined by Ewald test meal and the fractional method alternately four times before being judged as anachlorhydric, and classified according to the stomach condition most probably present. In the final analysis there were forty in which true cellular atrophy

* Read before the Section on Gastro-Enterology and Proctology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

was believed to exist, instances of people who at some time before were reported to have normal acid present in the stomach which was now definitely absent. Regarding these the focal infections shown in the accompanying table were present.

Of the head cases only pyogenic sinus conditions, badly diseased tonsils and distinct pyorrhea were considered significant. Chronic middle ear conditions and tooth apex infections were not included unless one or more of the former mentioned conditions also existed. The chest series were all tuberculosis with mixed infections in moderately advanced cases; and of the abdomen, the gallbladder, appendix, colon, renal, female pelvic organs and prostate disease made up the group. Other than the chest cases, infections were proved by operation in only two instances, and in these, infection was believed to be present. In the four nonseptic cases all means of examination could not prove the presence of focal infection. These cases of primary gastric cell atrophy with chronic focal infections were striking. In them it was noted that this stomach condition was more liable to occur because of the infection than could be proved in any other stomach entity. It, therefore, was believed that cause and effect were practical enough to be significant for presentation at this time and worthy of further study.

The stomach retains few bacteria that must enter it. It is supposed that persistence of acidity is inimical to their development. My observations suggest that the acidity is not so significant a factor in this as is the status of motility. Moreover, the acid factor is only significant with the simple fermentation organisms, for with the pathogenic types, such as the bacilli of the coli group, staphylococci and the various forms of streptococci, it is not. Perfect examples for the observation of this are found in hypersecretion continua (the so-called Peichmann's disease) and gastritis acidia. In these the acid secretion is high enough to inhibit an increased bacterial flora; still, in the majority of instances it does not do it. In perfect examples of these, both the bacteria and the leukocytes are increased, proving that there is pathology in the stomach mucosa, and that the normal acid does not inhibit the bacteria when local pathology is present. An argument may be made that in stagnant and achylic stomachs, like those seen in late cancer, the bacterial content in the stomach is high, but the bacteria met with here are only the fermentative and not the pathogenic forms. These organisms, then, are accidental, or better, secondary. A further argument might be made that stomachs which empty practically, even though a little slower, do not contain nutritive substance containing nitrogen and carbon for bacterial growth. Our observations have been that the stomach is rarely empty of every vestige of food. Even in normal stomachs a few meat shreds, starch granules, and mucus may be met with as late as seven or eight hours after meals. From these, but more especially in the stomach tissue, the bacteria derive sustenance for growth, and the more pathologic their nature, the surer is it that organic tissue gives to them the essentials for their livelihood.

Work was done on those patients that had been operated on to delineate an identical infection. This failed because of the multiplicity of bacteria met with in the focal infections and the stomach contents. In

practically all of the cases it was not possible to decide which biologic type or strain was associated in causative ways, but the organisms of the streptococci and bacillie classes occurred conspicuously in the focal infection and in gastric contents. Bacterial studies of test meals were made in the other anachlorhydric cases, and in those of normal and increased acidities. Standards of numbers of organisms per cubic centimeter of unfiltered test meals and gram-differential kinds were established, and it was found that in acid stomachs the bacteriology was nearly identical, depending somewhat on the status of motility. In the simple anachlorhydric cases more bacteria of the fermentative kinds were encountered, and in the noninfective and nonatrophic cases they were not pathogenic in kinds. In atrophic gastritis and the senile cases, the content was higher and tended to gram-negative pictures; but in the true or primary atrophies the content had distinct pictures in which large amounts of organisms, mostly the staphylococci, streptococci and streptobacilli, often actively motile, occurred as distinctive findings. So suggestive was this that diagnosis of this type of cellular atrophy in the stomach was being made by bacteria count and the study of stained specimens of test meals alone. Grown from different specimens of these test meals were *B. coli*, *B. proteus*, bacillus of malignant edema, staphylococci and various streptococci, pneumococci and the Comellan-King diplococcus. A gram-negative organism, streptobacillus in type, and grown best in 2 per cent. glucose bouillon, in some instances seems to have special significance.

In the cases of twenty-nine of the patients that were operated on, examinations of test meals were made one month and longer after operation, but no beneficial change in the bacterial pictures or acid content was noted. These and the four in which a focal infection could not be established were treated by vaccines according to the bacteria as they occurred conspicuously in the stomach contents of the individual case. In these twenty-three cases, fourth day injections, beginning with twenty-five million and rapidly increasing according to local and general reactions, were tried for twenty doses, the last being well into the billions, sometimes as high as 6. No benefit locally from the vaccines could be demonstrated. The patients that were operated on were benefited, but this was probably not local in the stomach, and no doubt was only such as came from the operations benefiting the general body. These patients were then tried on lactofarinnaceous diet, with large doses of alkalis and pancreas preparations, and daily lavage. On this plan of treatment improvement was noted, not only in the subjective stomach symptoms but generally as well, and represents, in my opinion, the best means of treatment.

SUGGESTIONS

Some one, a wise and observing biologist, I assume, has remarked that when any one talks of causation he hangs out a signal to the discerning that he has made an incomplete analysis. This philosophical criticism finds no field richer in examples than that of medicine. Although I have been at this work for three years, I really have no definite conclusions; instead I offer only suggestions in the hope of stimulating interest and further study, and these may be thus expressed:

1. Pathologic studies suggest that essential cell atrophy in the stomach is quite a common condition.

2. Cellular atrophy can be a true primary atrophy; and these instances should be distinguished from the forms secondary to chronic gastritis.

3. In primary cell atrophy the destruction is, in all probability, due to toxic effects from focal infections gaining lodgment in the spongy glandularis, or from bacteria culturizing in the stomach glandularis or stomach contents.

4. The bacterial studies of test meals are important in this connection, the organisms, particularly when actively motile in the test meals, being significant.

5. Distinction should be made between the pathogenic and fermentative organisms in test meals, not only because of an explanation of the achylia, but because of the suggestion that focal infection probably exists somewhere in the body.

6. Vaccines made from test meals are of no benefit in the cases, either subjectively or objectively, the removal of the focal infection being more important for benefit to the subjective stomach symptoms as well as to the body in general.

7. With the subjective stomach symptoms alone, the old method of treatment with gastric lavage as an addition to the lactofarinaceous diet and alkalis and pancreas preparations proved to be the best treatment, although in no case was there any return of normal acid or proenzymes.

8. When primary cell atrophy has taken place, the loss of gastric juice secretion is as permanent as when the atrophy is secondary to a chronic gastritis.

GASTRO-INTESTINAL DISTURBANCES IN PERNICIOUS ANEMIA*

FURTHER OBSERVATIONS

JULIUS FRIEDENWALD, M.D.

AND

T. H. MORRISON, M.D.

BALTIMORE

The relation existing between anemia and various gastric affections has been a matter of great interest for many years. As early as 1860, Austin Flint¹ called attention to the possible dependence of certain cases of pernicious anemia on certain degenerative changes in the gastric mucosa. In 1865, Samuel Fenwick² published a memoir on "Morbid Changes in the Stomach and Intestinal Villi Present in Persons Who Have Died of Cancer" in which he observed the disappearance of the cells in the gastric tubules, granular and fatty degeneration and atrophy, and an increased formation of connective tissue with a marked thinning of the mucous membrane, and with loss of flesh. Especially did this condition occur in persons dying with cancer of the breast. He explained the anemia accompanying this disease as possibly due to the changes in the gastric tubules of the stomach.

In 1875, Schumann³ described a case of progressive pernicious anemia in which the gastric mucous membrane was almost completely denuded of its epithelium and the gastric glands were poorly developed and

insignificant in number; mucous hemorrhages, increase of connective tissue and fatty degeneration of the muscularis and of the blood vessels were observed.

In 1877, Fenwick⁴ reported four cases of pernicious anemia in which atrophy of the gastric tubules was observed. Later, Nolen⁵ reported two cases of a similar condition; Quincke,⁶ one case; Nothnagel,⁷ one case; Brabazon,⁸ one case; Henry and Osler,⁹ one case, and Kinnicutt,¹⁰ two cases.

The opinion was held by these observers "that a primary atrophy of the gastric mucous membrane occurs and that in this lesion is to be found an explanation of certain cases of pernicious anemia." The reason for this conclusion is evident. The entire degeneration of the glandular elements of the stomach, together with the loss of secretion, appeared sufficient to explain the condition of the blood. It was noted, however, that an entire absence of gastric secretion could exist for a long period of time without impairing the general health of the patient. It is, therefore, impossible to conclude that gastric atrophy causes pernicious anemia; and the two conditions must be classified as a result of a common cause. Grawitz¹¹ has advocated the gastro-intestinal theory as the cause of pernicious anemia, believing this condition to be due to an intoxication. He is inclined to lay great stress on the achylia gastrica which is so commonly present in this affection. The objection to this theory is founded on the fact that achylia may be present for years without producing anemia; it is frequently present in other conditions, for instance, in malignant affections, or as a result of intestinal parasitic infections. Oestreich and Strauss¹² call attention to the histologic change observed in the mucous membrane of the stomach and intestine, occurring with much constancy in pernicious anemia, to which they attach much importance. The changes consist mainly of an atrophy of the glandular structures, and an accumulation of leukocytes in the submucosa. Notwithstanding the fact that the histologic changes show an apparent relation existing between the gastro-intestinal tract and the blood disease, they could not demonstrate a destruction of the blood by a poison generated by ordinary putrefaction in the intestine.

Following these observations, Martin¹³ and others studied the alterations in the intestinal mucosa in pernicious anemia. A marked thinning in the muscularis and submucosa was observed, and this condition was found in all sections from the duodenum to the colon. The microscopic examination showed an overgrowth of the interglandular tissue in the mucous membrane of the intestine, there being a richness in round cells in the early stages and poorness in cells, with fibrous formation in the later stages. The further the advance of the disease, the greater the compression in the glandular part. Bloch¹⁴ has published some experiments bearing on the etiology of pernicious anemia. Extracts prepared from the intestinal contents of patients in different stages of the disease were injected into animals without, however, producing any charac-

teristic symptoms from which definite conclusions as to the etiology of this affection could be reached.

Strauss¹⁷ also concluded that since neither ordinary nor artificial constipation is capable of producing the symptoms of pernicious anemia, the hemolytic agent, therefore, which produces the destruction of the blood cells in anemia must depend on some special change not present in ordinary putrefaction. Tixier¹⁸ describes the relation existing between gastro-intestinal disturbances and anemia and points to the slight alteration found in the gastro-intestinal canal in patients dying from anemia associated with intestinal conditions. He maintains that the blood changes in these cases must be explained by the formation in the intestine of a poison having both the power of destroying the red corpuscles and that of stimulating the blood forming organs. The latter power is at times exhausted while the hemolytic power is still active. Moffitt¹⁷ has suggested a protozoan infection as the cause of pernicious anemia.

It would carry us too far to draw attention to all of the various gastro-intestinal findings which have been observed in pernicious anemia by various observers. We need only call attention to the increase in eosinophil cells found by Lubarsch¹⁹ in the interstitial tissue of the gastric mucosa in all cases. On the other hand, Jurgens²⁰ called attention to a degeneration of the motor nerve elements of the intestine, which Blaschko²¹ described as an extreme degeneration of both Auerbach's and Meissner's plexus. From these findings it was concluded that in certain cases of pernicious anemia the primary cause is to be found in the destruction of the nerve elements of the intestine leading to functional disturbances and finally anemia. The evidence for this conclusion is, however, extremely insufficient.

The gastric secretion has been studied in pernicious anemia by a number of observers: H. H. Strauss²⁰ found free hydrochloric acid present but twice in a study of eight cases; and in twenty cases of Rosenquist, four cases of Morawski, and in eight cases of Strauss free hydrochloric acid could be detected in but 16 per cent. of the cases. Bloch observed that in the stage of improvement in pernicious anemia there is an increase of free hydrochloric acid; while Schumann²¹ found an absence of this acid even when patients had apparently recovered from the disease for over two years.

In a study of twenty-four cases of pernicious anemia, Stockton²² observed that eighteen patients were affected with gastric disturbances; while six were free of such disturbances, ten were constipated, eight had diarrhea, and in six there was an irregularity of the bowels. In eleven instances the liver was enlarged; in thirteen it was not; nine cases showed a dilatation of the stomach. In thirteen instances there was an absence of gastric digestion, in eight the gastric digestion was diminished, and in three it was fairly good. Five cases showed evidence of gastric catarrh. In six instances there was an absence of acid in the gastric contents, while the average of the total acidity varied

around 1:10. In three cases free hydrochloric acid was present in traces; in all others it was absent.

Austin²³ found an absence of free hydrochloric acid and of the ferments in his cases, while the gastric motility was diminished in most instances. He also

noted an increase of urobilin in the urine and of stercobilin in the feces; occult blood was also observed in the feces. Of the seventy-nine cases observed by Cabot,²⁴ only one presented hydrochloric acid in the stomach contents in any considerable quantity.

In 1912, one of us²⁵ presented a series of fifty-eight cases of pernicious anemia in all of which gastro-intestinal symptoms were noted. Since then we have collected eighteen additional instances, making seventy-six in all. Of the seventy-six cases there were sixty-four males and twelve females, the ages ranging between 30 and 65 years.

The symptoms manifested were loss of appetite, nausea, vomiting, indigestion (fullness, pressure, distention, pain), diarrhea and constipation.

Loss of appetite was observed in forty-seven cases, nausea in thirty-seven, vomiting in twenty-six, indigestion in forty-six, diarrhea in twenty-eight, constipation in thirty-five, and irregularity of the bowels in thirteen. The liver was enlarged in twenty-four instances, while in fifty-two it was not. Enteropneumosis was present in twenty-eight instances and atony of the stomach in thirty-four. Gastric catarrh was present in eleven cases. The gastric contents were examined in fifty-seven of the seventy-six cases. In forty-two of these there was an absence of gastric secretion (achylia gastrica). In eleven the gastric secretion was diminished and in four it was normal. In the forty-two cases with an absence of gastric secretion, the total acidity ranged between 5 and 16. In the eleven with diminished gastric secretion, the total acidity ranged between 18 and 41, free hydrochloric acid between 5 and 12. In the four with normal digestion the total acidity ranged between 44 and 65, free hydrochloric acid between 32 and 44. The gastric secretion was examined in eleven patients presenting an absence of free hydrochloric acid during the period of improvement in the state of the blood as well as of the general health; in none did the secretion return during the stage of apparent recovery.

We have also examined six cases of pernicious anemia according to the Rehfuss method of fractional analysis. There was in all a low total acidity ranging between 10 and 15 with an entire absence of free hydrochloric acid in every stage of the digestion. The Wolff-Jungmans test always presented low protein values, thus differentiating this condition from gastric cancer.

From a study of the seventy-six cases of pernicious anemia, it is evident that a large proportion of these cases are attended with gastro-intestinal disturbances as well as with an absence of gastric secretion; there is present an achylia gastrica in about 74 per cent. of the cases, and even in the stage of apparent recovery the gastric secretion does not return. In a smaller proportion of cases, 19 per cent., there is a marked diminution of the secretion, and in a few instances, about 7 per cent., it remains normal.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. BASSLER AND DRS. FRIEDENWALD
AND MORRISON

DR. MAX EINHORN, New York: Everybody knows that atrophy of the glands of the stomach exists, but it is very difficult in treating a patient to make a pathologic diagnosis. We also know that when extreme atrophy exists the prognosis is bad; while if there are only minute changes in the glands, usually a good prognosis may be made. When these studies of pernicious anemia were started by Fenwick, he had to deal with atrophy of the mucous glands of the stomach, and he said all those people had to die; and then people who studied the gastric secretion and found that there was

no gastric secretion, said: "Now, here there must be an atrophy of the glands, and all those must die." When I started studying medicine and found a young man who had no gastric secretion, I could not convince myself that he had atrophy of the stomach. That is the reason I protested against this promiscuous diagnosis. I termed that condition "achylia gastrica." That young man is alive yet, after more than thirty years. I have seen a great many of those cases since. So, while it is very wise and good to try and make a pathologic diagnosis, if you can do it, do it, but do not make a pathologic diagnosis when you are not sure, and make a bad prognosis when the prognosis may be good. With regard to this treatment of anemia, which Dr. Friedenwald brought out. It was agreed that in all of these cases there was no gastric secretion. Later on, when I studied that subject I found exceptions to the rule. I found some cases of pernicious anemia and most of them had real achylia, but there was a fraction that had genuine gastric secretion, indicating again that lack of gastric secretion is not the cause of pernicious anemia, perhaps quite the reverse.

DR. ARTHUR F. CHACE, New York: These two papers might have been labeled focal infection of the streptococcal type, as it involves the stomach and interferes with the digestive system, thus producing anemia. If we looked at the primary condition as one of infection that involved two different parts of the body, the alimentary tract and the hemopoietic system, it will clear up the atmosphere a great deal. Our attack in treating these conditions is along those lines. First, we eradicate the focus of infection; second, we improve the nutrition by treating the gastro-enteric tract. In anemia the improvements have been due to systematic treatment with hydrochloric acid, forcing alimentation, transfusion and by breaking up the patient's vicious cycle in the intestinal tract.

DR. MARTIN REIFFUSS, Philadelphia: I believe that we not only have focal infections as the causes of gastric disturbances, but that we can have a focal infection of the stomach itself. It is astonishing to note that the stomach is not frequently infected, because, first, the material is usually in movement; second, because there is acid enough from the gastric mucous membrane; third, because the gastric mucous membrane is vascular; and, fourth, probably because there is always free draining from the mucous membrane. A very interesting thing I investigated some time ago was the number of bacteria in the gastric contents. I found the easiest way to determine that was by microscopic inspection of the "Howard" test meals, following the ingestion of starch, etc. In the ordinary test meal with forty-five or fifty total acidity, there is an occasional organism of this type. A lower type of acidity in which there is a distinct decrease in the organism is also found. In a third group in which there is considerable progress in starchy digestion, and with it a large number of organisms of the same type, mucus, pus cells and bacteria are in the stomach contents. The interesting thing is this: At the height of the curve very little was found; at the bottom of the curve considerable material was found. There is a difference also in the character of that material. If you remove the material from the stomach in the morning you will find that in a true case of chronic gastritis in which the trouble is localized, there are bacteria, leukocytes and pus. You will find from mouth infection, throat infection and pulmonary infection distinct particles of pus like threads which float through the mucus. I have succeeded in three instances in isolating the organism from the stomach, preparing a toxin or vaccine, disinfecting the stomach and seeing the case clear up absolutely simply from purely specific treatment. I believe there is a focal infection of the stomach that exists as a specific cause of disease; second, this focal infection can be diagnosed; and, third, in some instances, at least, it is controllable. In these cases that are attended with considerable mucus, and sometimes with mucopus, and even in gastric cancer when the stomach becomes secondarily infected, I put the tube in and attach to it a rectal drip and allow that to drop disinfecting material over the stomach for a time. It certainly improves these cancer cases by keeping the stomach right. We have as much reason to keep an internal carcinoma clean as to keep an external carcinoma clean.

²⁵ Friedenwald, Julius: Boston M. & S. J. 167: 160-162 (Aug. 1) 1917.

DR. LOUIS LETRAK, New York: The chief clinical interest in atrophy of the gastric cells is the differentiation of the achylia which is usually present, from other conditions in which gastric secretions are also deficient or lacking. Cancer, neurasthenia and pure achylia, if there is such a thing, are to be differentiated. An absence of all the gastric ferments, including proenzymes, certainly points toward destruction of gastric cells. While from the standpoint of pathology atrophy of the gastric cells should be viewed with concern, still, I am sure, many of you have, like myself, seen cases in which gastric analysis showed a very low total acidity, absence of HCl, free or combined, with very poor result of rennin test and an almost negative Hammerschlag test for pepsin, and, despite all of which, the ungrateful patient refuses to be real sick. The possible compensating factors are increased motor activity and vicarious pancreatic and intestinal function.

DR. JOHN A. LIGHTY, Pittsburgh: In the clinic with which I am connected, we have refused to make a diagnosis of pernicious anemia where we have no achylia. We feel from year to year as we hold to this rule that we are making fewer mistakes in the diagnoses. In other words, in those patients in which we even find satisfactory roentgen-ray examination and find free HCl still present, or even the combined HCl we usually find the patient takes a different course from the ordinary cases of pernicious anemia. I feel that Dr. Friedenwald has given us a very valuable paper in that it shows that a case of pernicious anemia or so-called pernicious anemia with a certain amount of free HCl or combined HCl is a questionable case; and if the case is followed to the necropsy table it will usually be found that some definite pathology is present.

DR. G. A. FRIEDMAN, New York: I believe that achylia gastrica at the very beginning must be a functional disturbance, similar to diabetes which is at first a functional disorder of the Langerhans islets of the pancreas. The next step may be actual pathology; atrophy of the glands of the gastric mucosa in achylia; atrophy of the Langerhans islets of the pancreas in diabetes. When achylia gastrica has firmly established itself, all kinds of infection may set in into the stomach. It is known that the possibility of becoming infected with Asiatic cholera is slight as long as the gastric secretion is normal; and it happens very frequently that individuals will contract cholera while attending cholera patients when on a fasting stomach. What I wish to point out is that achylia predisposes to invasion of the stomach by bacteria, but is not caused primarily by infection. In regard to the connection of pernicious anemia to achylia, I agree with Dr. Emborn that pernicious anemia possibly causes the achylia. Of a similar origin the achylia in carcinoma of the stomach is probable, because we believe now that pernicious anemia is a malignant blood condition. Thus the essential achylia gastrica is primarily due to a functional disturbance, while the achylia in pernicious anemia and in carcinoma must be due to other causes.

DR. JACOB GUTMAN, Brooklyn, N. Y.: I am particularly interested in that class of cases which Dr. Bassler has thought best to classify as achylia gastrica endocrinica. Indeed, this condition has always been a question mark to me. Until recently, we were compelled to satisfy ourselves with its denomination achylia gastrica "nervosa," i. e., etiology of nervous origin, knowing no other basis. Lately, however, since we have become more familiar with the functions of the various endocrine glands, achylia gastrica has been given only as Dr. Bassler has shown, from a new viewpoint, the endocrine. During the past several years, I have been interested in studying individuals with achylia nervosa from their constitutional habits and in determining a possible connection between this disturbance and the tropism or constitutionality of the individual. I found that such individuals exhibit typical features which compel their classification into the adrenotrope class. You know that a study of somatic and functional features of individuals enables us to classify them into the adrenotrope, pituitotrope, thyrotrope or mixed habitus. From physiology, you also know the effects on the secretion of gastric juice and its suppression of such emotions (particularly of sudden) as fright, excitement, aggra-

vation, worry, etc., and that it is effected through the sympathetic, which is not only under complete domination but part and parcel of the suprarenals. The intimate relationship, embryologic and physiologic, of suprarenals and cerebral cortex explains the mechanism by which the emotional stimuli (shock, fear, anger) from the cortex are reflected through the suprarenals and their agent, the sympathetic, on gastric secretion. If you will observe your cases of achylia carefully, you will find no difficulty in coming to the same conclusions, as I did, that they are of the adrenotrope type. Female patients are of masculine build, males of the kind formerly styled status apoplecticus. You will find they are dark haired, dark eyed, ruddy complexioned, hairy skinned with nevi, pigmentations, very firm and stained teeth and numerous other characteristics, of adrenotrope origin. They are all more or less mentally easily susceptible to external influences and present types ranging from complete apathy to extreme nervous irritability. None, however, are of normal mentality, hence the term "nervosa" is not entirely a misnomer. I fully concur, therefore, with Dr. Bassler in his opinion when he speaks of the type of achylia gastrica designated as nervosa as endocrine in origin for in my experience these cases always exhibit some dysharmonism of suprarenal nature.

DR. ANTHONY BASSLER, New York: I am strongly inclined to agree with Dr. Eilhorn, that in cases of pernicious anemia the achylia is simply functional, or, as he expressed it, a resulting condition. Perhaps my two cases in which focal infection could not be demonstrated belonged to the group which Dr. Rehnus described. Whether a stomach can become primarily infected from pathogenic organisms we have not been able to prove. I believe that that is going to be difficult. I believe, with Dr. Gutman, that there are endocrinic cases of functional achylia that belong to the suprarenal group. I believe that the stomach condition in pernicious anemia is secondary, and in the two cases that we necropsied there was a definite primary cell atrophy of the type I described. We have had three very striking results with the use of hypotonic cells, cases of definite pernicious anemia, as definite as it was possible under the great variety of blood conditions to say that pernicious anemia was present. In those three cases there was a distinct *Bacillus purificans* infection of the bowel, although the bacilli were not present in any numbers in the canal. But here we had definite, marked infection, and we have believed that the benefit obtained has come from the use of lavage in that connection. In the study of the etiology of primary gastric cell atrophy in connection with focal infection cases, there are other conditions that can bring on primary gastric cell atrophy. I did not go into that. I would suggest that a differentiation in bacteriology be made, as far as it is possible, to decide whether the organisms are incidental, or belonging to the simple fermentation group, or whether they are primary and pathogenic.

Smallpox in China.—Chinese smallpox is usually classified among the diseases of children. It is described in excessive detail by native doctors. Fung's "Precious Bag" gives fifty-five varieties of the disease, eighteen rules of contraindications for treatment, several chapters of signs for predicting the result, and a host of preparations for its cure. Great stress is laid on the form, size, character, color, quantity, position, and time of appearance of the eruption. The complications enumerated cover all the sicknesses to which human flesh is heir. As to treatment, acupuncture, moxa, dieting, baths, charms, incantation, and various superstitious practices are employed in addition to drugs. But inoculation is chiefly relied on as the method of prevention. Human inoculation of variolous virus was first practiced in the Sung Dynasty (1022). The prime minister, Wang Tan, after having had several of his sons suffer severely from smallpox, was informed of the successful preventive inoculation practiced by a Szechwanese living at Ngo Wei Mountain. Wang Tan had a son inoculated and the inoculation proved very successful. This method was rapidly taken up and became very popular with the people.—*China M. J.*, 33:54 (Jan.) 1912.

EDUCATIONAL POSSIBILITIES OF THE
NATIONAL MEDICAL MUSEUM

IN THE STANDARDIZATION OF MEDICAL TRAINING *

CHARLES H. MAYO, M.D.

ROCHESTER, MINN.

The crisis through which the world has just passed was reached at a mighty cost of money, suffering, sorrow and life. It has freed the people of many nations, it is to be hoped that it has amalgamated the many peoples of our own; and if the world has been made safe, the tremendous effort will not have been made in vain. There will always be wars, but the waging of them will not be undertaken by the more highly civilized nations without just deliberation. The war has produced a mental quickening which has advanced our knowledge of the mechanical and the scientific far beyond that of a like period of peace. Our country is no longer isolated from other countries. Through science the world has become so contracted, as regards transportation, that whereas Columbus spent many weeks sailing from the old world to the new, it now takes but twenty-four hours to travel by air from the old world to the new, and but four and one half days by water.

The medical profession may be justly proud of the record made by organized medicine during the war. The carrying on of this war, above all others, was dependent to an extraordinary degree on the physician. This statement applies to the medical profession as a whole, which is alike the world over, there being little difference in the capabilities of the leading men. In the wars of the past, generals have deplored the losses due to disease, which were always greater than from injury in action and were looked on as a necessary and inevitable accompaniment of war. In this war there were more than two deaths from injury and its results to one of disease, and yet the world lauded the strategy developed by commanding officers. There have been but few instances of military strategy and almost no casualties among the higher officers in command. The real strategy of this war has been the control of disease by the men in the medical corps who reduced the loss of man power by preventive medicine, and by treatment controlled diseases that in the past were determining factors in the defeat of armies. The failure of the British in the Mesopotamia campaign was a medical failure due in part to lack of rank and attendant authority vested in the medical officers, and in part to army ethics, which made conferences difficult between officers of dissimilar rank. We need only to recall the yearly loss of 250 to each thousand men in the Crimean War, or the record of typhoid in the Boer and Spanish-American wars to realize the benefits of medical control of typhoid and of typhus fever when they started in Siberia. We must also recall the improved morale incident to the modern treatment and quick healing of wounds, whereby men were repeatedly returned to the ranks, instead of remaining permanently disabled and becoming a charge of their country, as in former warfare. Japan, one of the last countries to accept modern civilization, was the first to realize the importance of caring for the health of her troops; her medical officers were held responsible, and in consequence Japan

was able to defeat an apparently stronger nation. The exceedingly low disease record of the Japanese army was reduced more than one half in our training camps through the efficiency of that master of preventive medicine, Surgeon-General Gorgas, under whose direction the most efficient army medical organization was perfected that has ever been developed. The mortality rate of our troops in France was lower than that at home among civilians.

Long before our country became engaged in the struggle, hundreds of our profession, feeling the call of humanity, volunteered their services to France and England and served there faithfully and well, suffering many casualties. Our Reserve Medical Corps in France sustained 442 casualties; thus the percentage of losses of noncombatants equaled that of the infantry and artillery. Forty-six officers were killed in action, 22 died of wounds, 12 of accidents, 101 of disease, 4 were lost at sea, 7 were missing in action, 212 were wounded, and 38 were taken prisoners. For months before our country declared war, the first and best organization in preparation was the medical organization under the Medical Board of the Council of National Defense. These preparations were carried out for the purpose of aiding the Medical Department should war be declared. Practically one third of the active members of our profession, whose age, training and capabilities met the requirements of the Surgeon-General, were commissioned for service. Seventy thousand of the medical men not enrolled in the Medical Corps in active service were members of the Volunteer Medical Service Corps. In this group were included the members of the 5,000 local examining draft boards.

It is deplorable, and a blot in the history of this war, that the work of the American medical profession was not recognized by the general staff and that rank, according to responsibility, was withheld in most instances until the war was nearly or quite over. A comparatively long period of service in Washington enables me positively to state that the same unfairness toward the medical army officer still exists. Our government has maintained, at great expense, special places for the training of its army officers, even for their preliminary education, such as West Point for the Army, and Annapolis for the Navy. Students are given opportunity for service after graduation by continued training, maintaining the highest efficiency possible. The government in the past, however, has been at no expense in the training of the medical officers, but it has a postgraduate school for the purpose of training in the theory and practice of military medicine. No account has been taken of the fact that the men in the Medical Reserve Corps had had an average training of at least twenty years, and that their university course and medical course had cost not less than \$5,000 for each person. In spite of the injustice of rank and the inaccuracies of assignments, the members of the Reserve Medical Corps sacrificed freely and willingly that our troops might receive the best that medical education afforded. The work in hospitals, including general and special practices, should at least qualify the physician to be placed on a par with the line officer of the army who has had a similar number of years of inactive duty in times of peace. The soldier is rewarded or promoted for risk of life and personal valor; an officer who is given authority to command the destruction of life may have spent but a few

* Read before the Section on Surgery, General and Abdominal, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

months in a training camp, while the medical officer who is responsible for the preservation of life devotes many years to preparation. I believe that the necessity of higher rank is essential only as it represents authority and responsibility, and it is required by the civilian medical officer during his period of service. I feel sure that should military service again be required, those in authority will be compelled to give adequate recognition to the medical officers as a vital point of justice.

One last point and I am through with suggestions for the reorganization of army rules which have been well arranged to give a multitude of official positions in time of peace but are most cumbersome and fruitful of delay in time of war. If there must be a general staff, instead of assistant secretaries over divisions, it is highly important that the Surgeon-General's Office should have a representative in each division as a liaison officer.

Surgeon-General Ireland is a most worthy and capable commanding officer for the medical department; he had under his charge a volunteer service of enlisted men, nurses, sanitary corps, dentists and medical officers numbering 300,000; with the transference of the wounded and diseased, he had from 500,000 to 800,000. It is well to call attention to the small number of superior officers assisting the Surgeon-General as compared with the number maintained for corresponding thousands of able bodied men in the regular army.

The general training, discipline and broad education of the youth who participated in the war should insure a just and sane political management of our country for two generations. It is apparent from the rules of the organization of the veterans of this war that they have banded together for the purpose of giving to our country rather than taking from it. The protection against disease and the care of health during the training for war and during war will be recognized and demanded by them as their right, and the right of posterity in time of peace in order that in the future 36 per cent. of youth in the third decade of life will not be found incapacitated by disease and its results, should they be called to defend their country. The records of our draft boards, now made public, show a startling lack of interest on the part of our national, state and local authorities in their responsibility fully, and often even partially, to protect the people against preventable diseases and the accidents of industry. It is a poor government that does not realize that the prolonged life, health and happiness of its people are its greatest asset. The sum of money appropriated by the nation to expend for the prevention of diseases in man is, indeed, meager compared with the appropriations for the prevention of diseases in animals, and for the development of agriculture. Congress dare not investigate labor conditions for the purpose of maintaining a rational control of labor hours, and to control the value of labor in proportion to the investment. It is conceded, of course, that the manufacturers must be encouraged, and that small business operations only must be controlled by congressional act.

Because of the high cost and rapid turnover of labor, manufacturers, however, are recognizing as a necessity the protection of the industrial workers. The newer methods of treating injury, as developed by the war, will prove of the utmost advantage in caring for the accidents of industry. But many hundred cases of

typhoma, and thousands of cases of hookworm, in fact, all forms of disease that can be prevented, controlled or cured, still exist. The serums which have been used in the prevention of certain diseases, such as typhoid, typhus and tetanus, have now become commercialized, and their widespread use certainly places them beyond the criticism of the ignorant. Colonel Russell of the Regular Medical Corps deserves great credit for being the first to free the army of any nation from typhoid.

The laws of civilization signify progress and efficiency along scientific lines. Such progress and efficiency is due to the initiative of comparatively few persons who serve as a stimulus both to the professional and to the lay public. Public demand is the only true stimulus for tradesmen and professional men alike. This can be advanced only when the nation adopts the slogan "Educate the public."

The standards of the medical profession have been raised from time to time, and great strides are being made to further the progress, wholly through the efforts of its members. Hospitals are being standardized, surgery is being standardized, and everywhere the subject of sanitation and hygiene, dentistry, school inspection and child welfare work is receiving more attention than ever before. From the lessons learned through the war we may now hope to have government standards of all scientific progress. There is no national control of education to develop Americanism. It has been shown that eight and one half millions of our people of more than 10 years of age are uneducated, and 70,000 of our young soldiers could not read nor write. This is not startling, as we are habituated to ignorance; but to have this secret become known to the world is humiliating to those devoted to foreign missions, and will surely be the basis for the appointment of a cabinet officer of education, who will undoubtedly deal with the medical aspect of health problems of education by instituting another medical board in Washington to overlap the functions of a dozen similar powerless boards. Human life and health have been so cheap that it did not seem necessary to safeguard them until we learned how many of our youth in the third decade were physically incapacitated for army service. Through the psychology of war and by coordination of effort may it not be possible to better many conditions with regard to health problems? We must secure a certain degree of health; state or socialized medicine by which to control its development is inevitable.

The government has dabbled in medical affairs at enormous expense for what has been accomplished. Every cabinet position, and many smaller boards, bureaus and advisory committees in Washington, probably as many as eighteen, deal with certain phases of medicine. Thus under the Treasury Department is the Public Health Service; under the Agricultural Department, pure food and drugs; under the Department of Commerce, health statistics; under the Department of the Interior, the insane not otherwise cared for, amounting to a large number; under the Department of the Bureau of Labor, the accidents of industry, housing, sanitation and child welfare, all under their various divisions, subboards, and committees, none of which will coordinate or give way. Their duties overlap and the expense is great. England is now establishing a ministry of health with supervision of all the educational problems relating to health, sanitation and

preventive medicine. Medicine has been tried and proved to a degree that will enable it to stand comparison with any other effectual work of our government. Why not, therefore, establish a cabinet officer of health, and unite, or at least coordinate with efficiency of management, all of the diverse medical activities?

Undoubtedly great good will come through educational publicity by the development of the National Medical Museum in Washington, an institution which, until recently, has been conducted with an appropriation of but \$5,000 a year. It is true that the officers in charge have accomplished much with this meager sum. They have maintained a record of the progress of medicine of past ages and have accumulated many valuable historical specimens. The accumulations of the present war will make the collection modern, and one of the best in the world. I believe that these medical records of the war will be of the greatest value, not only to the glory of medical accomplishment, but also as a means of interesting and educating the public in scientific matters pertaining to health and disease. The museum now houses the splendid medical library of the Surgeon-General's Office. We can visualize a series of like departments, one to be devoted to the missiles of the present war and the character of wounds produced by them, fully illustrated by plaster casts, wax models and drawings; another department to show all the diseases and injuries of bone, with methods of repair and treatment; another department to represent the diseases and injuries of the respiratory system; another, the nervous system, etc.; each one amplified by animated drawings and moving pictures which will mark an epoch in the teaching of preventive medicine, and especially of surgery. There will be a department to demonstrate all the diseases common to man and animal, also those in which insects are the carriers or the immediate hosts for the diseases of both man and animal. In this department will be taught the prevalence, dangers and prevention of tuberculosis, glanders, actinomycosis, etc., as familiar types of a large variety of diseases, and showing the disappearance through control of yellow fever and malaria. The dentists will have a department in which to demonstrate the dangers of focal infections as the cause of chronic and recurring diseases, and to show the results of the neglect of teeth, dangerous types of dentistry, and the best recognized methods of treatment. The department for the curious anomalies and freaks of nature, now the sensational feature of the institution, will be shut off from public view and used only for teaching purposes.

It is probable that the recent graduate in medicine is but 30 per cent. efficient. Realizing this fact, some of our advanced universities do not give a degree until after the completion of one year's hospital service.

To raise our standard of medical instruction and organize a trained Medical Reserve Corps, 10 per cent. (approximately 200) of our medical graduates each year should enter the Army Medical Corps for practical instruction for a three year period with lieutenant's pay the same as at West Point. Nine months should be given to military instruction and field service; nine months to public health service, sanitation and hygiene; nine months to graduate work, and a like period to hospital intern service. If this plan could be developed, a wonderful regular Medical and Reserve Corps would be the result.

The Walter Reed Hospital, built and named in honor of that great martyr to medical progress, should be made the most efficient hospital in the country, and one in which standards of medicine should be established. This hospital, for the most part temporarily constructed, has a capacity of 3,000 beds; it should be replaced largely by permanent construction. Millions of dollars have been spent in Washington by Congress and by the district boards for hospital treatment and maintenance; hundreds of thousands of dollars are spent each year. Surgeon-General Ireland is endeavoring to coordinate the hospital work, the medical instruction, and the laboratories of the museum. It is highly important that he should have the support of the medical profession. While it will cost several millions of dollars to develop such an institution, it will repay many times by the direct return in increased efficiency in the care and protection of our American army, and, through education, in the care and protection of the health of the American people.

NEUROLOGIC SEQUELAE FOLLOWING ACUTE RESPIRATORY INFECTIONS*

WILLIAM H. ROBEY, JR., M.D.

Assistant Professor of Medicine, Medical School of Harvard University

AND

HEIMAN CARO, M.D.†

BOSTON

The etiologic factor in the cases cited in this report was difficult to determine and has caused some doubt as to the most appropriate title for the paper. The first case occurred during a period when a small number of cases developed in the camp characterized by a general bronchitis and malaise. The illness was mild, and many cases were so slight that the patients were cared for by the regimental surgeons and were not sent to the base hospital. The initial illness in the first case of the report was apparently mild, and the patient was not admitted until four weeks later, when the neurologic symptoms appeared. The second case appeared during an epidemic which lasted for about six weeks, and existed in several army camps in this country and Europe. For lack of a better name, and because of our ignorance of the etiology, it was called "three day fever." Eight hundred and fifty patients were admitted, and of these 500 entered the hospital between April 12 and April 20. One hundred cases were studied intensively, clinically and bacteriologically.

The characteristic symptoms were: onset with chill or chilly sensations, 72 per cent.; headache, 93 per cent.; general malaise, 92 per cent.; pain in joints and chest, 90 per cent.; cough, 62 per cent.; backache, 51 per cent.; sore throat, 21 per cent., and pain in eyes, 12 per cent. The physical findings were: redness of throat, 51 per cent.; rales scattered through the chest, 50 per cent.; redness of eyes, 11 per cent., and herpes facialis, 5 per cent.

On admission the patients felt very ill, but within twenty-four hours the majority were anxious to return to duty. The complications were slight in the hundred

†† Captain Caro died of pneumonia in January, 1919, at Base Hospital No. 107.

cases studied: bronchitis, 25 per cent.; pneumonia, 1 per cent.; and otitis media, 5 per cent. (The clinical data were collected by L. E. Lucens, First Lieutenant, M. C.)

In the bacteriologic study many organisms were found to be present, but the predominating ones were a nonhemolytic streptococcus in the throat and the nasopharyngeal cultures, while *Micrococcus catarrhalis* was second in frequency. (The bacteriologic studies were made by G. A. Wislocki, First Lieutenant, M. C.)

Involvement of the nervous system as a sequelae following acute infections of the upper respiratory tract is by no means uncommon. Mild neuritis and neuralgias following such infections are frequent, and generally present a good prognosis. Neural complications with fatal termination are comparatively rare.

REPORT OF CASES

CASE 1.—History.—R. F., a white man, aged 22, was admitted to the base hospital, Dec. 19, 1917, with a diagnosis of "paraplegia, incomplete, and urinary distention."

The family history was negative except that the mother had died of cardiac disease when the patient was quite young. He was of subnormal mentality (moron). He had had measles, diphtheria and scarlet fever in childhood. In 1916, he had an attack of pleurisy involving the left chest. He denied any venereal disease or alcoholic indulgence.

Four weeks prior to admission, he was taken ill with rhinitis, tonsillitis, malaise and cough. At the end of a week he was able to return to his work as a cook, apparently fully recovered. About two and one-half weeks later, or four days prior to admission, he noticed that his left lower extremity was weak and "dragged." Two days later the right was similarly involved, and he had great difficulty in walking. On the succeeding day (prior to admission), he had acute urinary retention and incontinence of feces.

Condition on Admission.—The chief complaint was of pain above the symphysis pubis and inability to walk. Physical examination revealed chronic pharyngitis, hypertrophied and retracted tonsils, a small-sized left cervical gland, and scattered, medium moist rales throughout both lungs. Neurologic examination revealed markedly exaggerated knee and ankle jerks, with sustained bilateral ankle clonus, and the Babinski response on the left only. On attempting the plantar reflex, there was a tendency to flex the lower leg ("guard phenomenon"). Pain sensation was diminished from the waist downward, and there were also vague paresthesias. The pupils were equal, regular, and reacted normally. There was no nystagmus nor diplopia.

Course of Illness.—December 21, a complete paraplegia was present. Knee and ankle jerks were absent. From a line midway between the ensiform cartilage and the umbilicus to the toes, pain and thermal sensations were absent, but tactile and muscle sense were preserved. The tendon reflexes of the upper extremities were present and equal. Bladder retention and rectal incontinence continued.

December 25, muscle and tactile sensations were found to be absent in the area described, and there was now complete anesthesia from the ensiform downward.

December 26, complete anesthesia had advanced to the fifth intercostal space, and the patient began to complain of severe congestive pain. Since his admission to the hospital, his temperature had ranged from 100 to 102 F., always rising at night. The condition of the pharynx and tonsils continued as at entrance. Expectoration became more profuse, but there was no change in the physical signs. There was a flaccid paralysis of the lower extremities, and sphincter disturbance remained unchanged.

December 29, since the foregoing note the patient had become steadily worse. Complete loss of sensation now extended to the clavicles. There was motor paralysis also of both arms. Respiration became Cheyne-Stokes in character. The patient became markedly nansated, lapsed into coma and died.

Laboratory Findings.—The spinal fluid was under slight pressure and showed 100 cells per cubic millimeter, with as many red corpuscles and a trace of globulin. The Wassermann reaction was negative. The blood count was 10,000 white cells, of which 70 per cent. were polymorphonuclear leukocytes and 30 per cent. mononuclears. The urine was straw colored and cloudy, with a specific gravity of 1.017, a heavy trace of albumin, no sugar, and a large number of white cells (which may have been due to repeated catheterizations).

Necropsy Protocol.—The heart and lungs appeared normal. The vessels along the entire course of the spinal canal were found to be congested, and markedly so over the thoracic region. At the level of the third, fourth and fifth thoracic vertebrae, the cord was very soft and swollen, especially at the level of the fourth, or in the region of the sixth and seventh thoracic nerve segments. Cultures from this region were sterile.

Histologic Examination of the Cord (by Dr. F. B. Mallory).—Blocks of the formaldehyd-fixed cord were zenkerized, and paraffin sections from six different levels were stained by the eosin-methylene blue method. All except the uppermost level showed varying degrees of the same pathologic lesion, namely, large and small areas of degeneration and destruction of the nerve fibers and of their myelin sheaths. In the degenerated areas, the nerve fibers had often entirely disappeared, but in places they were present and much swollen. Where the lesions were at all marked, the remaining tissue (chiefly stroma) was infiltrated with large numbers of endothelial leukocytes, containing vacuoles evidently because of their having been filled with fat and myelin. The endothelial leukocytes occurred diffusely in the tissue and also packed in the walls of the blood vessels. In a few places lymphocytes were present in small numbers, and, in the part of the cord where softening was obvious macroscopically, a few small clumps of polymorphonuclear leukocytes were present, chiefly in the neighborhood of the small blood vessels.

In a section through the lumbar region, the lesion involved the white matter extensively on both sides of the median fissures, and occurred also in foci in some of the lateral tracts on one side. In a section through the dorsal cord, about two thirds of the white matter was degenerated or entirely destroyed. In the softened area, practically the whole cord was involved. Some of the ganglion cells in the gray matter showed more or less extensive retrograde changes, but no necrosis.

Diagnosis.—Transverse myelitis.

CASE 2.—History.—J. B. M., a white man, aged 26, was admitted to the base hospital, April 7, 1918, with the diagnosis of "acute influenza." The family history was negative except that his mother had died of pulmonary tuberculosis. The patient had had typhoid fever in childhood. In 1912, appendectomy was performed, apparently without drainage. In 1914, the patient spent several months in a sanatorium for pulmonary tuberculosis, but asserted that he was told that he did not have any active lesions. During the months of February and March, 1918, he had two attacks of severe, crampy pains in the muscles of his arms and legs, lasting but a few minutes each time. He denied syphilitic infection. From the age of 20 to 24 he had been very intemperate, he said, but for the preceding two years he had been a total abstainer.

Four days prior to admission (April 3), the patient became ill with photophobia, headache, nausea, vomiting and general malaise. He continued at his duties until the day prior to his admission, when he felt much worse and had a very irritating cough. (His symptoms were similar to those of an epidemic of acute respiratory infection, called influenza, then rife in the camp.)

Condition on Admission.—He complained chiefly of the symptoms mentioned above. Physical examination disclosed a few scattered rales throughout both lungs, but especially at the right base posteriorly. His temperature was 101.4 F. Neurologic examination was essentially negative.

Course of Illness.—April 10, the patient complained for the first time of weakness, numbness and inability to extend his

legs. There was a slight tenderness on pressure over the nerve trunks. The knee jerks were absent, but the ankle jerks were present and equal. The normal plantar reflex was present. There were no Chaddock nor Oppenheim signs, and no sensory disturbances. The temperature was normal, and continued so throughout the course of the disease.

April 19, the condition had slowly grown worse. The patient had considerable nausea and hiccup, which were slow in clearing up under dietary measures. Neurologic examination revealed ankle and knee jerks absent, normal plantars present, no ankle clonus, abdominal reflex absent, and the tendon and bone reflexes of the upper extremity present and active. No changes in sensation were noted except that deep sensibility was increased, and that Lasèque's sign was present. Vague annoying paresthesias in the form of intermittent crampy muscle pains caused considerable discomfort. They were confined to the peroneal and anterior tibial muscle groups. The patient could adduct and abduct the thigh, but flexion of the thighs or extension of the legs was impossible. There was no toe drop. To faradism, the quadriceps extensors gave no response, while the calf and hamstring groups reacted slowly. The muscles of the upper extremities reacted well to the current, but the hand grips were weak.

April 26, the patient continued to grow worse. Anorexia was now practically absent. The inability to extend the forearms and the weakness of grasp steadily increased. The patient complained of blurring of the vision as regards distant objects, but ophthalmologic examination failed to reveal any process involving the retina, media or eye muscle balance. There was no facial paralysis. There was a slight huskiness of the voice, and examination of the larynx disclosed a weakness but not a true palsy of the vocal cords. The accessory muscles of respiration were not affected. The triceps reflex was absent on both sides; the other upper arm reflexes were diminished in intensity. To faradism, the triceps muscles of neither arm reacted at all. The abdominal reflex was absent, but the cremasteric was present. There was no change in the condition of the lower extremities or in the sensory reactions. There was no bladder nor rectal symptoms. A slight tenderness was present on pressure over the sciatic, the anterior crural, the internal cutaneous (of the thigh) and the musculospiral nerves at their points of emergence on both sides. At this time these nerves appeared to be chiefly involved with the sciatic to only a slight degree.

April 30, the condition of the extremities remained as described in the previous note. There were no sensory disturbances except the crampy pains mentioned. The accessory muscles of respiration showed no involvement, but the breathing had become slightly irregular and labored. The patient complained of pain in the chest and of sensations of constriction. Examination of the heart and lungs detected nothing abnormal. The pulse, however, had increased from 96 to 120.

May 3, respiratory difficulty gradually increased, and evidence that the diaphragm was involved was quite evident. On the day preceding, the temperature rose to 101 F., and there was evidence of a beginning terminal pneumonia. The patient died from respiratory paralysis plus the toxemia of the pneumonic process, the sensorium being clear to the end.

Laboratory Findings.—The urine was clear and had a specific gravity of 1.027. It contained no albumin nor sugar; the sediment was negative. The spinal fluid was under normal pressure, 1 cell per cubic millimeter, with a very faint trace of globulin. The Wassermann reaction was negative. Blood examination revealed that white cells, April 8, were 11,300 per cubic millimeter, with 73 per cent. polymorphonuclears, 4 per cent. transitionals, and 23 per cent. mononuclears; April 12, 7,800, with 63 per cent. polymorphonuclears, 7 per cent. transitionals, and 30 per cent. mononuclears; April 24, 9,200 with 70 per cent. polymorphonuclears, 6 per cent. transitionals, and 24 per cent. mononuclears. Red cells were 5,600,000 per cubic millimeter.

Necropsy.—A detailed report cannot be given, but no gross lesions of the brain or cord were found. Dr. Mallory examined the cord histologically but was unable to make a diagnosis.

CONCLUSION

The first was a clean-cut case of acute ascending myelitis, in which the only etiologic factor appeared to be an acute respiratory infection antedating the neurologic symptoms by nearly three weeks, but which had never entirely cleared up, as evidenced by the chronic pharyngitis and the infected tonsils still present. The second case was more difficult to diagnose, although the etiologic factor was undoubtedly a respiratory infection of unknown origin. We have already shown how varied were the bacteriologic findings in the group of cases to which the second patient belonged.

Of interest is the very selective action of the toxin—the nerves supplying the extensor muscles of the body being more especially involved, while, peculiarly, the wrist-drop and the toe-drop were absent. The picture from day to day was suggestive of an acute Landry's and, later, perhaps of some form of the muscular dystrophies; but, the symptoms taken en masse, the diagnosis of acute polyneuropitis seems unquestionable. The fact that such complications may follow comparatively mild infections of the upper respiratory tract is a matter that always warrants grave consideration and, as is well known, a very guarded prognosis.

ABSTRACT OF DISCUSSION

DR. CHARLES A. ROSEWATER, Newark, N. J.: I would like to ask if Dr. Robey has heard of cases of sudden death following influenza or three days fever. In some of these cases the illness was so mild that the patient was not even confined to bed, and yet these individuals died suddenly. A man about 50 years of age awoke at midnight and complained of pain in the heart; he died before he even had a chance to take a drink of water. Inquiry revealed the fact that he had been slightly indisposed for one day a week or so previously, although he did not stop work. Two weeks after the death of this man his 22 year old daughter dropped dead after eating Christmas dinner. No history of previous illness could be obtained. I have heard of other cases of sudden death following the influenza epidemic. An ophthalmologist informed me that he had seen several cases of strabismus following influenza. This may be a condition similar to post diphtheritic paralysis, and it is not unlikely that there are more of these cases than have been reported.

DR. W. H. MAYER, Pittsburgh: There is no question as to the secondary manifestations of these respiratory affections. There is also no question that the epidemic of influenza was one which may or may not have been due to the influenza bacillus. But many other organisms were present and the lesions of the nervous system which followed were colored by the predominance of this or that type of toxin. I am prone to regard the cases of sudden death, to which Dr. Rosewater referred, as being due to cardiac collapse. It has long been recognized that no matter how mild the primary infection is, the myocardium always suffers, and in my experience those persons who were profoundly ill and who had a long convalescence, especially after influenza, suffered less than those whose illness was of a shorter duration and who had insufficient rest in bed. All manner of mild nervous states with fatigability, in some cases approaching what has been called the neurocirculatory asthenia syndrome, were present. I believe that in these cases the disturbance is primarily cardiac. I realize that I am treading on dangerous ground when I attribute the past epidemic to the influenza bacillus although the work of Klotz and others seems to have satisfactorily established this point despite the presence of the nonhemolytic streptococcus which they have shown to be a secondary invader. By its close association with the influenza epidemic, I regard the epidemic encephalitis as in all probability due to the causal factor of the primary infection. That these cases all present the pathology as so clearly outlined yesterday by Dr. Bassoe

I cannot believe since many of the cases of rather complete involvement have cleared up too suddenly. I especially remember one case in which there was a bilateral third nerve palsy and a bilateral seventh nerve involvement. Curiously, there were exaggerated reflexes and a paralysis of a spastic type in the right arm, with absence of reflexes in the right leg, and in the left leg an exaggeration of the reflexes, with normal reactions in the left arm. This condition persisted for several weeks and then recovered quite rapidly. There are many phases of nervous involvement which accompanied the epidemic of last year, whether called influenza or not, which were not peculiar or different from what has been observed in former epidemics except as regards the encephalitis. There is still, perhaps, some question to discuss concerning the reason for the severity of brain stem symptoms which involve lethargy and stupor which occurred in this last epidemic and are different from the involvement of the nervous system as witnessed in former epidemics.

DR. MAX H. WEINBERG, Pittsburgh: Like Dr. Mayer I am inclined to connect these two cases with encephalitis lethargica particularly the first case, in which there was an increased cell count in the spinal fluid. It would seem that these two cases belong to the polynuritis group of encephalitis which was reported in the Local Government Bulletin of London, No. 121. Unlike the investigators of Europe who state that there were no changes in the spinal fluid in the cases in New York, we found that a great majority showed an increase of cells, mainly lymphocytes. We have found as high as 400 to 600 cells per cubic centimeter. It would be interesting to know whether the other cases in this series have shown other symptoms, such as ocular or facial palsies.

DR. ALBERT GORDON, Philadelphia: Apart from cardiac organic disease, sudden death speaks very strongly of a sudden lesion in the mesencephalon. In the recent influenza epidemic I had an opportunity to observe a very large number of cases with a great variety of neurologic symptoms. I grouped under the name encephalitis lethargica all cases presenting besides the somnolence peripheral nerve involvement in which all the cranial nerves were more or less affected. It would seem that the cases reported by Dr. Rosewater and others belong to one category, namely, disease of the mesencephalon. As to the anatomic basis for it we must refer to Marie's work in which he speaks with great emphasis of the involvement of the gray matter around the third and fourth ventricle, also of the degenerative changes of the locus niger. As to the somnolence reported in encephalitis lethargica, there is nothing especially new about it as this affection has been known many years. In Rivier's clinics reference is made to a large number of cases following infectious diseases, such as paratyphoid fever and pneumonia. Gayet long ago referred to somnolence as being associated with a lesion in the mesencephalon, and he wanted at the time to describe a special somnolence center. By analogy we must draw the inference that all these cases, whether reported as encephalitis lethargica or as "fluence" and other infectious processes, belong to one category with variations.

DR. VICTOR H. ROMY, Jr., Boston: As to the cases of influenza referred to by Dr. Rosewater, we did not have any. I do not know how the epidemic of influenza was regarded in this country. In France there seemed to be evidence that it was caused by the influenza bacillus. In most cases it was a profound toxic disturbance due to the hemolytic streptococcus. In the experiments of transmitting the influenza bacillus the conclusions were very unsatisfactory. I believe these were probably due to some toxin. Regarding Dr. Rosewater's case it is as to the other cases, the only other encephalitis which was *entis media* in a case with prominent fever. Only two patients presented neurologic signs and symptoms.

Encephalitis as a Disease. One of the most serious problems of the present day is the treatment of holocephalus. It must be characterized as methodical, and when it has attained to such a degree that it can no longer be ignored. HARRISON, N. Y. (1919).

PROGRESS OF VENEREAL DISEASE CONTROL*

C. C. PIERCE, M.D.

Assistant Surgeon-General in Charge of the Division of Venereal Diseases, United States Public Health Service

WASHINGTON, D. C.

To indicate briefly a few of the actual achievements of the division of the Public Health Service entrusted with the direction of the campaign against venereal diseases in cooperation with the state agencies of the country; and to indicate briefly, also, what the year's experience has taught concerning the future development and advance, is my purpose in this paper.

It will be recalled that on the declaration of war the U. S. Public Health Service was given the responsibility, by Congress and presidential order, of supervising sanitary conditions in the zones created around military establishments. The comprehensive program promptly outlined, whereby this task might be fulfilled and the health of the fighting forces protected at the avenues of civilian communication, included, among other measures, the proper supervision over water, food and milk supplies; the proper disposal of human excreta; the elimination of breeding places of flies and mosquitoes, and the efficient control of communicable diseases, including gonorrhea and syphilis.

FORMULATION OF A PLAN OF CONTROL

For the control of venereal diseases in these zones, special measures were necessary. These measures were based on the findings of other countries during the war, as they attempted control of venereal diseases, and on special investigations showing an inevitable relationship between liquor and prostitution, and prostitution and venereal disease. The measures had the authoritative support of Sections 12 and 13 (afterward Chapter 14) of the Selective Service Act, Section 12 prohibiting the sale and distribution of liquor to the troops, and Section 13 (afterward Chapter 14) controlling the activities of prostitutes in and near the zones. But it was not sufficient to protect the soldiers, sailors and skilled laborers within the boundary lines of cantonments or industrial plants.

Previous war history had indicated definitely that epidemic disease is contracted not so much in reservations under military control, as in municipal areas with unsatisfactory sanitary control. It will be recalled that five-sixths of the venereal infections among men who entered military service had been incurred in civil communities before they reached camp. Hence the program for combating syphilis and gonorrhea was formulated on a nation wide basis and was put into effect with the increasing cooperation of state boards of health.

Jan. 2, 1918, the following telegram was sent to all state health officers by the Surgeon-General of the United States Public Health Service:

Control venereal infections in connection prosecution of the war constitutes most important sanitary problem now confronting public health authorities of United States. Plan of control mailed you today. Request your cooperation forceful enforcement same. Venereal infections should be made reportable, and quarantinable. Means of diagnosis and cure should be provided. Campaign wisely conducted publicity should be launched. Please inform me your action in premises.

*Read before the Section on Preventive Medicine and Public Health at the Seventy-Ninth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

This was followed at once by a letter confirming the telegram and further stating that:

It is evident that the prevention of venereal infections in the military population is largely dependent on the degree with which these infections are prevented in the civil community. This imposes on the civil health authorities the duty of forcefully attacking the venereal problem on the basis of the control of communicable disease . . .

With this letter was forwarded an outline, a working plan, tentative, since no plan could be at once devised which in all phases met the necessities of every state. The outline of that plan is as follows:

1. Epidemiology of venereal disease.
 - (a) Peculiar to the human species.
 - (b) Chronic diseases.
 - (c) Spread by contact—not necessarily sex contact—chronic carriers.
 - (d) Very prevalent in all classes of society.
 - (e) Most prevalent in classes of low inhibition.
2. Control of venereal disease
 - (a) Depends on the control of infected persons.
 - (b) Control of infected persons depends on knowledge of their whereabouts. This may be determined by:
 - (1) Morbidity reports by serial number (in the case of private practitioners), name to be disclosed when infectious persons cease treatment. Case then followed up by health department, which enforces quarantine act.
 - (2) Morbidity reports from venereal clinic and hospital.
 - (3) Legal enactment necessary to secure morbidity reports.
 - (4) Enacting and enforcing ordinance requiring pharmacists to keep record (open at all times to health department) of sales of drugs for the prevention and treatment of gonorrhea and syphilis.
 - (c) Object of this control is to prevent contact between infected and noninfected persons.
 - (d) May be obtained by:
 - (1) Quarantine of infected persons.
 - (2) Cure of infected persons.
 - (3) Education of general public to avoid direct and indirect contact with persons infected or presumably infected.
3. Quarantine of venereally infected persons.
 - (a) Those who desire and can afford treatment
 - (1) These are instructed by their physicians and theoretically are thus quarantined.
 - (b) Those who desire cure and cannot afford treatment.
 - (1) Means should be provided for free treatment.
 - (a) Accurate diagnosis.
 - (b) Dispensary relief.
 - (c) Hospital relief.
 - (c) Those who are careless or wilful in the distribution of these infections through promiscuity.
 - (1) These, for the most part, are the ignorant or the criminal classes. A careful physical examination of all persons entering jails or other public institutions should be made, those found infected to be isolated, either in a special hospital or under a probation officer who enforces dispensary relief.
4. Cure of venereally infected persons.
 - (a) Establishment of venereal clinics by health authorities.
 - (1) Federal, in zones in close contiguity to cantonments.
 - (2) State, in situations in which local authorities refuse or fail to establish a clinic.
 - (3) City, particularly by those cities in which commercialized or clandestine prostitution flourishes for the patronage of soldiers but is beyond the authority of the secretary of war.
 - (4) Country, in thickly settled rural communities.

- (b) By the creation of new, or the utilization of existing, hospital facilities.
 - (1) For the treatment of those who volunteer for treatment.
 - (2) For the obligatory treatment of persons under control of the courts.
- (c) By legal enactment.
 - (1) Declaring the venereal infections to be quarantinable.
 - (2) Substituting confinement to hospital for confinement in jail in the case of those convicted by courts and having venereal infections.
 - (3) Substituting remanding to a probation officer for the imposition of fines.
 - (4) To carry out 2 and 3, it is necessary that all persons arrested be examined by the city physician or other authorized person.
 - (5) By arrest of acknowledged and clandestine prostitutes by policemen.
5. Public education regarding venereal diseases.
 - (a) Relieve the problem of all moral and social issues and place the campaign solely on the basis of control of communicable disease.
 - (b) Propaganda of wisely conducted publicity.
 - (1) Through public meetings addressed by forceful speakers.
 - (2) Through public prints.
 - (3) By placarding public toilets, placards to emphasize dangers of venereal diseases and to recommend prompt treatment, either by a competent physician or at the free venereal clinic.
 - (4) By follow-up work by social workers.
 - (5) By the education of infected persons.
 - (a) By physicians in private practice
 - (b) By the venereal and clinic hospital.

CLINICS AND LEGISLATION

The first step in this plan was the opening of clinics. The necessity for prompt protection of the health of military forces had placed on the resources of local communities a greater demand than they could fulfil. The first United States government clinic for the treatment of venereal diseases was opened in November, 1917, at Newport News, Va., one of the principal ports of embarkation. This clinic was operated under the joint auspices of the U. S. Public Health Service and the American Red Cross. A chain of twenty-six such clinics was rapidly established in the extracantonment zones, and their work was emphasized by the program put into effect in adjacent cities. Later, as state boards of health accepted their allotment of federal funds (presently to be mentioned) for control of venereal diseases, other clinics were established until, at the present time, fully 250 clinics where venereally infected persons may receive treatment without charge are listed throughout the country.

Another part of the program promptly put into operation was that of legislation. In March, 1918, *Public Health Reports* contained regulations whereby the state departments of health might control venereal diseases, regulations which were approved by the Surgeon-Generals of the Army, Navy and Public Health Service, and in less than a month thirty-two states had put the suggestions into active operation, either by adopting new regulations necessary to meet the situation, or by taking laws already on their statute books, out from the "dead letter" classification.

NATIONAL APPROPRIATION

The activity and cooperation achieved during the first months of the war were greatly stimulated by act

of Congress, July 9, 1918. At that time the Army appropriations bill was passed, Chapter 15 of which created an interdepartmental social hygiene board and a division of venereal diseases in the U. S. Public Health Service, and carried an appropriation of \$4,000,000 for the essential activities and extension of this work during the two-year period ending June 30, 1920. The special section making this appropriation is familiarly known as the Chamberlain-Kahn act. From this time the activities of venereal disease control centered in the new division of the service created under the terms of this section.

The responsibilities assigned to this division were threefold: first, to study and investigate the cause, treatment and method of prevention of venereal diseases; second, to cooperate with state boards of health in carrying through a program of control and prevention; and third, to promulgate and enforce interstate quarantine regulations covering the travel of venereally infected persons. The \$1,000,000 appropriated under Section 6 of the Chamberlain-Kahn act, for allotment on the per capita basis to the various state boards of health, was promptly allotted to those state boards of health which fulfilled the regulations issued by the Secretary of the Treasury, containing requirements and standards. These regulations included the following points:

1. Syphilis and gonorrhea must be reported either under a state law or a state board of health regulation having the effect of law.

2. An officer of the Public Health Service shall be assigned to each state receiving the allotment, to cooperate with the state health officer in supervising venereal disease work in the state.

3. The allotment itself shall be expended on standard fines, 10 per cent. being assigned to administration, 50 per cent. to treatment, and 20 per cent. each to repressive and educational measures (the reprint containing the regulations in full is included in the exhibit of the service).

No financial condition was attached to the allotment for the first year. To receive an appropriation for the coming year 1919-1920, each state will appropriate a sum equal to that received from the federal government. It is of interest to know that up to the first of June thirty-two states had already appropriated the quota entitling them to receive an allotment for the second year of this fund.

In addition to this congressional appropriation, a further stimulus was given to the work of the service by the presidential order of July 1, 1918, placing all civilian public health activities conducted by federal agencies under the Public Health Service. An exception was made of the Bureau of Labor Statistics, which was investigating vocational diseases, shop sanitation and hygiene.

ONE YEAR'S WORK

The first year's work of the division has emphasized the cooperation with state boards of health, in a nationwide effort to eradicate venereal diseases. In this effort, forty-four states are at this time actively cooperating. Of the four remaining states, two have not yet passed the necessary state laws or regulations which would bring them under the provisions governing the allotment, but may do so before the close of the present legislative session.

Regulations controlling the interstate travel of venereally infected persons were promulgated, Nov. 22, 1918. This, it will be recalled, was another duty

of the division defined in the Chamberlain-Kahn act creating it. The third obligation, to study the causes and the treatment of venereal disease, will be met as accumulated records and case histories supply the authentic social data for tracing deep seated causes and providing treatment of the needed scope and duration. Meantime, more is known of the causative organisms and the mode of transmission than is being put into actual practice for prevention. The immediate necessity was for action. Research in sociological as well as medical fields is also especially provided for in the terms of the Chamberlain-Kahn act.

MEDICAL ACTIVITY

The four lines of the division's activity may be generally described as medical, educational, legislative and social.

Conspicuous in the medical work has been the establishment of the clinics for the diagnosis and treatment of venereal disease. The rapid increase in number of these clinics has already been mentioned; but the need for establishing yet other such centers of advice and treatment cannot be overemphasized. It is futile to educate people on the subject of venereal infections if no place is provided to which they may go in their aroused interest or anxiety.

The relation of the venereal clinic to other clinics of the department of health or health centers, their location in parts of the city accessible to various social groups, their provision for service in evening as well as daytime hours, and their equipment and personnel are matters of greatest importance in the control of syphilis and gonorrhea.

No less important, also, is a further deepening of the interest of general hospitals in this work, in order that beds may be available for patients who must remain under detention for treatment, since they cannot or will not take care of themselves; and also for venereal patients needing special medical or surgical care during their period of infectivity. A striking development of the work in certain hospitals in which wards are provided for patients of the "carrier" type is the introduction of vocational work, as well as recreation of suitable kind, in order that the patient who for the first time, perhaps, has learned the significance of this disease, may not simply be cured physically and then set free to resume a life of prostitution (if that be the source of infection), or allowed to return to society not better safeguarded than before against the physical temptations of the old existence. Even the preliminary reports of such attempts available thus far are encouraging. A certain business firm sends experts to one such hospital ward to train the patients in their particular industry, carries them by number on the payroll, and accepts them as regular employees when they are discharged from the hospital.

This is no utopian state dreamed of and vaguely hoped for. It is a practical application of vocational therapy to this new group of patients, whose potentiality to society for good or ill is most significant.

In hospital and in clinic alike the opportunity for thorough mental examination is evident. During the period of observation and treatment of venereally infected patients, subnormal types should be separated from the normal, and provision made either for the permanent care of those whose mentality is too low for them to face the social and economic demands of life, or for the training of those who may attain a

degree of economic independence under adequate supervision. At this point it is not necessary to do more than mention the relation of this program to efforts for better state reformatories and for the industrial farms where, in addition to vocational training, the benefits of continual outdoor life may combine for the rehabilitation of the patient.

Before passing from this mention of medical measures in the venereal program, a word must be added concerning the urgent request sent to physicians by the service that they cooperate in reporting gonorrhea and syphilis under their state laws and regulations, as other communicable diseases are reported. The decision is with the individual state or city whether these reports shall be made by serial number or by name, and the procedure varies in various localities. That the serial number is perhaps in many circumstances the more satisfactory method is explained by the fact that the responsibility for the patient represented by the serial number is left precisely where it belongs, namely, on the individual physician who is treating the case. This is of advantage to the physician in that it allows him to study the case from beginning to end. It is of advantage to the patient who has given his confidence to the physician.

A special opportunity for highly trained work is increasingly evident as the clinics multiply and develop. This is for follow-up work, which the service believes can best be done by graduate nurses with additional training to meet the social aspects of the problem.

There is evidence, too, that as in the case of other well established clinics, the venereal clinic is becoming a place of special consultation and of experience and training for physicians and older medical students, and that it will play a conspicuous part in the teaching of syphilology.

EDUCATIONAL OPPORTUNITY

When the service speaks of educational measures the term implies explanation and, when necessary, warning to the public with all truth and frankness concerning these diseases so long held to be "unmentionable." It is maintained that the information given to the public should be frank without being unnecessarily frightful; that it should emphasize the means of preventing infection, recognizing, however, among these means, not simply treatment itself, but the no less truly therapeutic measures of improved moral, educational and social conditions.

In special relation to the teaching of children on matters of sex and reproduction, the educational material published by the service emphasizes the importance of home teaching. The consensus of opinion (as evidenced in many conferences) of teachers from schools, colleges and universities of many sections of this country is that courses of sex hygiene in schools should be not distinct in themselves, but that the information should be given simply and unobtrusively in connection with courses in botany, biology, civics, history, etc. The value of poster exhibits and motion pictures is proved practically beyond question—when the subject-matter is of the highest standard.

It may be of interest to note at this point that one of the subjects for research for which Chamberlain-Kahn funds have been allotted is to the department of psychology of a leading university to provide for the thorough investigation of the effect on various audiences which view them of moving pictures on subjects of social hygiene.

LEGISLATIVE ENACTMENTS

Legislative measures sincerely and unflinchingly enforced are at this time necessary in order to control the wilful and ignorant persons of the community who, themselves infected, will not take precautions to protect their neighbors. The right of the community to protect its health has long been recognized; and citations from various legal writers of unquestioned authority were made early in this campaign for the control of venereal diseases by the attorney general of the United States. Enforcement of sanitary measures should not create an issue with educational and moral appeal. The moral value of whatever will best safeguard the community at present, and therefore make for the best in posterity, cannot be questioned.

It is evident that no arbitrary grouping of these measures is attempted or possible. Medical effort is in the best sense educational. Education in this field includes medical and legislative information, and both are vitally social, in addition to the activities of a distinctively sociological nature, on which the permanent control of syphilis and gonorrhea, as of other communicable diseases, depends.

COMMUNITY AND COOPERATIVE EFFORT

The undertaking is a community undertaking. The individual physician cannot from his office follow all his cases of gonorrhea and syphilis to the successful termination which means control and prevention of disease. Nor can the health officer alone, even with his special administrative machinery, entirely meet the situation. There is needed opportunity to draw on the resources of the community and to take advantage of aroused public sentiment and civic loyalty in prosecution of this campaign, and the social agencies of the community have never been so alert to help intelligently or criticize acutely as they are found to be today.

That this is not theory, but an actual, practical possibility, finely demonstrated in the past two years, may be indicated even by mention of some of the various civilian groups in active cooperation with the service and the state boards of health. Employers of labor have responded to the program for introducing into their plants educational literature, and have established clinics—sometimes several firms in a small town uniting to meet the expense of the clinic.

Groups of working men and women have not only welcomed the literature and lectures in the industrial plants, but have also expressed through their official organizations appreciation and desire to cooperate. Chambers of commerce, rotary clubs, churches and church organizations, women's clubs, parent-teacher associations—these and many other groups in the community stand ready to serve by influence and active work or financial support.

When the work was first organized, an association of retail druggists, representing about 8,000 of the 47,000 retail druggists of the United States, offered its cooperation in this important work. A card was prepared, approved by the druggists' organization and mailed to pharmacists all over the United States by the Public Health Service. This card contained an appeal to the druggists to support venereal disease control work by pledging themselves to discontinue the sale of venereal disease nostrums, and also by refusing to prescribe remedies for the self-treatment of venereal diseases. The response was gratifying. The druggists

not only agreed to cooperate as they were asked to do, but also agreed to hand each customer who applied for a remedy ordinarily used in the self-treatment of venereal diseases, a circular advising the sufferer to seek competent professional service, either from a practicing physician or at a venereal clinic. In this plan approximately 32,000 druggists are now actively cooperating.

Perhaps this rapid résumé of the work of eleven months will at least suggest the year's progress, in its total accomplishment and in its direction.

THE PHYSICIAN'S PART

In closing this paper I desire to emphasize the peculiar relation to the future of the program which is borne inevitably by the physician himself. Into the hands of many of you has already come that recently published little volume, prepared for use in this campaign by Dr. J. H. Stokes of Rochester, entitled "Today's World Problem in Disease Prevention." In his preface Dr. Stokes says:

It is no longer possible for the individual physician to maintain the isolation and the arbitrary powers and responsibilities which were his in primitive times. . . . A partnership between intelligent and well informed public opinion and the physician as leader is the logical ultimate expression of the trend of the times. . . . The physician as a leader, acting alone, is helpless. . . . To make every intelligent man, woman and child a legionary in the organization of the public health, some of the knowledge so long sedulously kept as the property of the profession of medicine must be imparted to the rank and file.

The opportunity of the physician, the challenge to the physician, of this determined undertaking to control syphilis and gonorrhea is unmistakably evident. Consider, for instance, the following truths: It is the physician who must teach the future physician. The demand for a higher grade of teaching in syphilology has been heard, not in this country alone; it has come from the medical profession of every country which, in the past four years, has borne the burdens of war.

It is the physician who must finally teach the people, whether in his own office or in the clinic consulting room, what they must know and do to control and prevent venereal disease. To no other person but a physician comes such an opportunity as that of the patient's first visit for offering enlightenment, for teaching a truth which shall endure and for impressing on him his responsibility toward his family and neighbors. In this task, personality, sincerity, skill and humanity are taxed for the remaking of the individual. Contact not only with the patient but with the patient's family, the social group and community means multiplying the physician's power to control disease. Physicians make, as it were, a system of social engineering, whereby breeding places of syphilis and gonorrhea may be drained, more easily than was supposed possible. The examination of the family of an infected person is not often refused when frankly and tactfully suggested by the physician. Very often it is even asked for by the patient.

This procedure leads yet farther. It means often the discovery of carriers, of sources of infection in the community, sources which the physician himself may not be able to control, but which becomes the concern of the health officer duly acquainted with them by the reports of the physician.

Again, it is the physician who after all reduces the number of "lost cases," always a clinic or dispensary

problem. The patient who is treated simply as clinical material will naturally not desire to return for a second experience of the kind. But he will quickly discern the humanity of the man who treats him, the human spirit of the institution to which he goes. Skill, prime essential though it be, is not alone enough to insure the full realization of a clinic's possibilities. Tribute to the men who have proved this true!

And it is again the physician who will maintain high professional standards of clinic and hospital. It was long ago whimsically remarked that the physician who helps develop the clinic is cutting his own financial throat; but this, of course, is untrue, and that a new view of clinic service prevails today is evident. The physician is asked to give much. There is also much for him to gain. Besides the rich opportunity for studying varied types in a clinic which receives, for instance, 1,000 venereal cases a month, there is to be gained also a knowledge of the peculiar social backgrounds of syphilis and gonorrhea. These must be known and reckoned with. On the control of social causes depends all permanent control of the diseases.

Finally, the physician may be assured that his participation in various phases of this limitless effort, scientific and social, will insure for him public support of an intelligent and appreciative type that is a thing unique today. Other national campaigns against tuberculosis, trachoma or hookworm disease, all have had social and economic complications of their own. But in the case of syphilis and gonorrhea there is added to these social and economic aspects of the problem the handicap of age-long false tradition. We face a very slowly yielding prejudice against even discussion of these matters. We face the difficulty of directing human wills and instincts. Such a demand on the physician, and on every intelligent member of society, would seem appalling were the possibilities not testified to by a remarkable demonstration of what has already been done.

Preventive medicine is one of the contributions to the world of the medical profession. To the medical profession the world, in this after-war day, turns in confidence for the solution of its deepest problem.

ABSTRACT OF DISCUSSION

DR. WILFRED H. KELLOGG, San Francisco: California was the first state in the field in this work. Owing to the fortunate existence of an emergency fund the governor was enabled to make an appropriation of \$60,000. A bureau was organized and in operation as early as August, 1917. Its program was based on the usual classification or division of work into three principal parts, education, law enforcement and treatment. We might more accurately arrange these activities in a more extended manner, such as elimination of foci of infection, education, law enforcement, rehabilitation, prophylaxis and care of the feebleminded. Under the first heading will come the treatment of infected cases, quarantine, establishment of clinics and reporting of cases. Perhaps, under this heading should also come the division of rehabilitation, although this problem must be handled in an entirely separate and distinct manner. I refer to the rehabilitation measures capable of application to prostitutes, which it is possible by law enforcement measures to bring under the jurisdiction of the health department. The enforcement of law against prostitution is of extreme importance in controlling the spread of venereal diseases, and yet I feel that our best position is to take advantage, wherever possible, of activities of this sort in local communities by seeing to it that women taken up by the police are properly detained and treated, but not to be too closely related with the pushing of activities in this direction.

I think we should greatly favor law enforcement, but it would be a mistake to be associated too intimately with organizations which are related exclusively to the moral side of the problem.

Prevention of infection by prophylactic treatments in civilian communities is very difficult to carry out, and it is this reason rather than the moral objections that are brought against it that should weigh in the decision as to whether or not it is to be added to our list of activities.

Dr. A. E. CHASE, Texarkana, Ark.: I find that the railway employee is, perhaps, unusually exposed to venereal infection, because of his mode of life and because of his being away from home a great deal. When I took charge of the health and welfare of many thousands of these men, I felt it a duty to open a venereal campaign, on two lines. The U. S. Public Health Service helped us out wonderfully. On the educational line, I ran up against a stumbling block. A committee was appointed by the Railroad Administration and informed me that this educational campaign should not be carried on, because they had been ordered by their superior officers not to carry on the campaign among railway employees because the unions would be peeved by such a procedure and labor troubles would result. I am sure that those who originated that order did not understand the railway employee, because I have met many thousands of them in talking over this program, and as a result I have not only got them to endorse this campaign, but they have asked that additional means be taken to carry on the campaign, and that amounts be withheld from their monthly salary to carry on the work. It shows that the railroad employee is a man, and that he understands his own faults and that he is willing to do all he can to promote health conditions himself. He is not a man who is unusually touched by that class of educational propaganda. On the medical side there is a very difficult question. This class of cases is very hard to handle. The prophylaxis side of the question is the most important, and I hope that the U. S. P. H. Service will help us arrange stations not only for railroad men, but for all others who need this service.

Dr. FRANKLIN L. GRAM, Buffalo: I would like to ask Dr. Pierce whether he would advise us to keep records and reports of these cases by serial numbers. We have been carrying out a venereal program for the past eight years in Buffalo; we have a clinic and a hospital for the treatment of the disease; we give arsenphenamin free; we give examinations free, and we help in every way along the prophylactic and curative line. After an actual experience of eight years, I can say that we would be swamped if we were to conduct our work by serial numbers. We record the real names and real addresses, but the records are confidential, the same as we carry our tuberculosis records. We had the same trouble originally with tuberculosis records, but by keeping them confidential and letting the public know that they were confidential, we succeeded in getting all the facts. We also work together with the police and courts.

There is another matter of very great importance, namely, maliciousness. I had a report recently, made by telephone of a young lady who was accused of spreading venereal infection. Investigation and examinations showed that she was innocent and the accusation malicious. I fail to see how we are going to control venereal disease or make any progress in that direction, with all due respect to the federal and state government, by reporting and recording cases by serial numbers.

Dr. I. D. RAWLINGS, Chicago: In Chicago we receive the report without the name or address of the patient and we find that it works out very well. We have in our ordinance a provision that the physician must report in this manner, and if the patient discontinues treatment, then it is the duty of the physician to furnish the office with the name and address of the patient. We then look up that patient and require him to get under treatment with some physician, or if he is not able to pay, he must go to the clinic and take treatment. I do not see but what this method works out as well as any other would. In the report of the case, we also get the data as to where he contracted the infection, so that point is covered by our method equally as well as if we had the name and address of the patient. Under all plans of

reports the patient is apt to give a false name or a wrong address or both. One thing that I hope I will get out of this discussion that will help us in our work is how to induce the patient to give the physician his true name and his correct address, so that if the patient discontinues treatment and the name and address of the patient as given to the doctor is sent by the physician to the health department, we can locate him without difficulty. The patient can give a false address under any system, and you do not discover it until you try to locate him. These people cannot always be located. That is the chief trouble we are having in Chicago, and I do not see how we can remedy this difficulty by either system. Venereal disease patients will give a wrong address to their physician, and the result is that the health authorities are unable to act as they should.

Dr. C. C. PIERCE, Washington, D. C.: Dr. Kellogg mentioned the place of prophylaxis in part of his program for venereal disease control. The Public Health Service believes that in the clinics prophylactic or early treatment should be given to those who apply. We do not, however, believe in the establishment of prophylactic stations as such, similar to those organized and maintained during the progress of the war, for several reasons. One is that you cannot conduct such a station properly without causing a great deal of antagonism on the part of certain groups of society, and another is that you have no control over persons who take the prophylaxis, as was the case in the army. In regard to Dr. Chase's statement that some railroad officials had told him not to carry on an educational campaign among unions—that is a very remarkable statement, because the Railroad Administration is very much in favor of his program. Practically all of the labor unions have welcomed most heartily the introduction of educational methods and are helping to carry on themselves. With regard to patients not staying under treatment: That is one of the results to be accomplished by the reporting of venereal diseases.

In regard to reporting by serial number or by name: That is left entirely to the local health authorities to choose the method they think gives the best results, and that is the only way it can be done. All data giving the sort of information which is of use to the health officer can be secured by either system of reporting. Health officers and government officials and others must not feel that they must conduct this campaign in all its details by themselves, but that they should utilize the present great desire on the part of all persons in the United States to do something to increase the efficiency of our country. The central controlling agency in the venereal disease program is the state board of health, but we can utilize existing agencies in all parts of the country, and they will be of great material assistance to the state board of health or the city board of health in carrying out a comprehensive program for the prevention of venereal disease. A very important phase is controlling the carrier and treating those who are already infected because in no other way can venereal diseases be prevented.

Dr. José Rizal, the Hero of the Philippines.—One of the greatest personages in the history of the Malayan race was Dr. José Rizal who was born near Manila in 1861. He was educated in the Philippines and in Spain where he obtained the degrees of doctor of medicine and philosophy and continued his studies at London, Paris, Brussels and in Germany. His writings were mainly devoted to arousing the people of the Philippines to throw off the yoke of Spain, especially his two satirical novels exposing the malgovernment and despotism of Spanish rule. They were published in Spanish in Germany and are said to have had a great influence on the thought of his country, and caused him to be branded by Spain as a traitor. On his return to the Philippines he was seized and executed, Dec. 30, 1896. His birthday, June 19, has since been celebrated there with increasing enthusiasm as he is considered the greatest national hero of the Philippines. His career was described in the *British Medical Journal*, 1:829, 1907, and the latest *Literary Digest*, July 26, gives a short poem he wrote in English the night before his execution. He could write in six languages, and had a real knowledge of Latin, Russian and Dutch.

heart and pleura as decided and circumstantial as the indications furnished to the surgeon by the introduction of the finger or sound, in the complaints wherein these are used.²

It is interesting to note that Laënnec speaks of Auenbrugger's long neglected discovery of percussion as one of the most valuable in medicine, and emphasizes the value of the combination of percussion and auscultation.

To the medical student and young physician there should be a powerful inspiration and stimulus in the brief life of Laënnec. He was assiduous and systematic as a student, and began to make independent observations when barely 20, thus attaining a favorable distinction early. He lectured on pathologic anatomy, wrote critiques and reviews and took an active part in medical society work, presenting specimens and communications before he obtained his degree. Having graduated, he devoted himself to his practice and to his medical studies, in the course of which it became clear to him that to know disease we must know the underlying changes, and that this knowledge can be gained only by thorough, systematic, combined clinical and anatomic observations. And so he made his immortal discovery and continued his observations "with a degree of success, and a fertility of results, much more remarkable than the discovery itself."

ZINC AS A NORMAL CONSTITUENT OF FOODS

Less than a quarter of a century ago, iodine assumed a new physiologic significance through the discovery of its constant presence in the body as a constituent of the thyroid gland. Compared with such elements as calcium or chlorine or iron, the quantity of iodine occurring in the organism is exceedingly minute. In contrast with the hundreds of grams of lime, for example, a few milligrams of iodine represent the entire complement of the latter constituent; nevertheless it has already established a claim for indispensability in the normal functioning of the body. Indeed, there are few more striking illustrations of the profound potency of minute portions of any element than are afforded by the iodine-containing thyroxine which Kendall has succeeded in isolating from the thyroid gland.

This experience with iodine has paved the way for a more respectful attitude toward suggestions of the possible physiologic rôle of other elements which have heretofore not been counted among the essential or even the potent constituents of the body cells and fluids. The occasional statements that certain metals like copper and arsenic are to be found regularly in the tissues were usually regarded as due to experimental errors of analysis or to accidental contamination. The

tendency of the body at times to store metals, such as those mentioned, in the liver has become familiar from medicolegal observations of toxicologists.

The report by Mendel and Bradley¹ of Yale University that certain marine mollusks found in Long Island Sound regularly contained zinc directed attention to new possibilities with respect to that element. Copper had long been known as a constituent of some of these lower forms, being a part of the protein compound responsible for the "blue blood" which many of them may exhibit. Ocean water is known to contain small traces of the less common elements, such as arsenic, copper, lead and zinc. The most conclusive indication that zinc is a normal constituent of some of the marine forms rather than a chance contamination due to the presence of foreign elements in their environment has been furnished by Phillips.² He found zinc in specimens collected at the Tortugas Islands far removed from any possible contamination of the sea water.

The experts of the Bureau of Chemistry in the U. S. Department of Agriculture³ now report that zinc is present universally in oysters—at least in those grown in Atlantic waters. It is probably always associated with copper. The amounts of metals present appear to have no direct relation to the body weight of the oyster or to the quantity of ash-forming solids it contains. The presence of very large amounts of copper is usually revealed by a blue or bluish green coloration. Such oysters invariably contain large amounts of zinc, though not in uniform proportion to the copper. The blue coloration serves, therefore, as a reliable indicator of the presence of large amounts of such metals. Hiltner and Wichmann remind us that the oysters from certain localities have gained unfavorable notoriety because of the amounts of copper they contain, frequently excessive enough to impart to them a strong turquoise-blue color and a metallic flavor, and to yield a decided copper coating to bright iron when boiled with it in dilute acid. They add that since the amounts of copper and zinc found in apparently normal oysters from different localities vary so widely, and since there seems to be no uniformity in the ratio between their copper and their zinc content, it would seem that oysters are capable of taking up amounts of these metals beyond their immediate physiologic needs.

It seems justifiable, in the light of the latest analyses by Birckner⁴ at the Bureau of Chemistry, to regard zinc as a normal, or at any rate common, constituent of many foods. Unexpected though the information may be, ordinary market milk averages

about 4.2 mg. of metallic zinc per kilogram. The zinc content of milk from individual cows varies somewhat in different animals. It is highest during the early part of the lactation period. Birekner reports that a given volume of human milk evidently contains considerably more zinc than an equal volume of cow's milk; and it would appear that the zinc content of human colostrum is lower than that of later milk. These findings are of special interest in view of the fact that the total mineral matter of human milk is only about one-third as high as the mineral matter of cow's milk. Hens' eggs contain an average of 1 mg. of zinc per egg, the metal being contained in the yolk alone. Cereals may also contain zinc.

One quite naturally inquires what may be the physiologic significance of such by no means negligible quantities of an element regularly present in important foods like milk and eggs. Are we to conclude that zinc is not merely an accidental constituent but a regular and perhaps essential ingredient of protoplasm? And what is to be said of manganese, which is reported present, though in smaller quantities? These are new questions abounding in a special interest because some of the elements here concerned, as well as arsenic lately reported present in most oysters,³ are known to have a potency that has long since placed them in the category of useful drugs.

THE COMPLEMENT DEVIATION REACTION IN TUBERCULOSIS

For a number of years, continental and American laboratory workers have endeavored to elaborate a reliable technic, based on the deviation of complement, for the diagnosis of tuberculosis. The clinician would welcome such a test to the degree that it would shift the burden of diagnosis to his laboratory co-worker. But the test, to be useful from this point of view, would have to be accurate almost to the point of infallibility; doubtful, borderline reactions would defeat its very object. Perhaps it is our good fortune that the realization of such an ideal is not in prospect—fortunate so far that its inherent tendency would be to make our diagnosis and clinical judgment in tuberculosis less exact and reliable rather than more so. Tuberculosis is the disease of all others that requires sagacious clinical judgment, along with discreet management; judgment based on all available facts—on a sane evaluation of the physical examination and the history of the patient, of the roentgen finding, of the sputum examination, of the reactivity to tuberculin, of the clinical course—certainly never on a single laboratory finding such as the complement deviation test.

The Wassermann reaction has had the benefit of two quite fortuitous conditions that have not been operative in the test as applied to tuberculosis. When

the Wassermann reaction was negative in cases that seemed clinically syphilitic, we were able to use the simple therapeutic test without great delay in the diagnosis. In the second place, despite the fact that the immunologic premises underlying the conception proved untenable, the technic remained practically fixed and soon demonstrated its usefulness and applicability.

In the tuberculosis fixation test there has been so far no agreement as to the proper method of carrying out the reaction. The greatest divergence has been observed in the preparation of the antigen. Whole and macerated bacteria, autolysates, extracts and filtrates, tuberculins and chemical fractions of tubercle bacilli have been used, and all with a not inconsiderable divergence of end-results at the hands of different workers, even when using identical antigen preparations. In sputum-positive cases the reaction has been positive in from 70 to 95 per cent., leaving a number of clinically active cases with a negative reaction. On the other hand, there are found positive reactions among apparently normal persons (young adults without clinical evidence of tuberculosis in any form and with no suggestive history).

Brown and Petroff¹ in a study correlating clinical and laboratory experience find the test of greater value to them as a control of the therapeutic regimen than as a diagnostic measure. It parallels the subcutaneous tuberculin reaction in that a negative reaction in the tuberculous individual is of more value than a positive one in determining which patients need treatment. They have found the reaction of value, too, in predetermining which patient will be benefited and which harmed by exercise and activity.

Lewis² has critically studied the reaction and has come to the conclusion that certain inherent defects will limit its usefulness. He suggests some modifications of the technic, however, such as increasing the time of fixation and increasing the quantities of complement and antigen in the effort to overcome the merely transient binding of complement that has possibly been interpreted by some workers heretofore as true deviation. It is his impression that it is unsafe to apply the reaction to the diagnosis of tuberculosis unless as a matter of confirmation of a clinical decision.

While Lewis notes that the common constituent of all the extractive antigens is alcohol soluble and more or less thermostable, some investigators (Wilson, von Wedel, Stoll and Neuman) use a lipid-free bacillary antigen, bringing into the foreground the problem of the relative importance of the lipoids and the proteins as specific antigens. While the research of Warden³ would place the greatest emphasis on the fats and lip-

oids, Small's⁴ work with lipid-free antigens would have to be interpreted in a way directly opposite.

Dyche and Much, it will be recalled, based their theory of "partial antigens" in tuberculosis on the supposition that the antibodies were of two varieties, both demonstrable by complement deviation. The one type was formed against the lipoids of the tubercle bacillus; the other against the proteins. They proceeded to immunize their patients with the object of increasing whichever type of antibody was found to be deficient.

It is evident that the reaction in its present stage cannot serve the physician as a foundation for his diagnosis. As confirmatory evidence it has some value. In a case with doubtful signs and symptoms and a continued negative reaction, the probabilities for the nontuberculous nature of the ailment are increased, while a persistently positive reaction would, in such a case, strengthen the presumption that we are dealing with an active lesion. With these limitations recognized, the test is useful.

DIET IN RELATION TO THE TEETH

The importance which the so-called focal infections have lately assumed as sources of disease has brought new prominence to the relation of the teeth to such infections. Indeed, pyorrhea alveolaris has tended to overshadow the far more widespread defects of carious teeth in which the conspicuous damage penetrates rather than surrounds these structures. If further evidence of the almost universal incidence of dental caries were needed, the records of the systematic examination of pupils in the public schools would testify to the degree of prevalence of teeth defects. The underlying causes are still unknown. They have usually been sought in local bacteriologic conditions within the mouth, if one may conclude from the emphasis that dentists place on oral hygiene. They seem not to realize that the presence of bacteria in itself never causes disease: we have millions of bacteria in our intestine and still thrive. What harm do the micro-organisms do in the mouth?

Evidently much depends on our powers of resistance. Disease of many sorts is the outcome of the presence of micro-organisms along with the lack of resistance or immunity factors. Facts in harmony with such a hypothesis seem to have been brought to light through the recent researches on scurvy. Zilva and Wells,⁵ who have had unusual opportunities for studying scorbutic animals at the Lister Institute in London, have convinced themselves that the mildest degree of scurvy which could just be discovered at the postmortem examination produced well defined

changes in the structure of the teeth; and in their numerous examinations they have not observed a single exception to this statement. In advanced cases of scurvy, in guinea-pigs and monkeys, the teeth were apparently sound, but useless, since they had been loosened by the gradual absorption of the cement membrane of the alveolar sockets, which had left exposed that portion below the neck. As a result, Zilva and Wells state, there must have occurred that periostitic pain or something analogous which follows in the case of human patients who are suffering from shrunken alveoli. These teeth also presented, in addition, all the appearances of the changes of senility.

The British observers regard the most striking changes in the teeth brought about by a scorbutic diet as a sort of fibroid degeneration which they designate as "fibrosis." It is believed that the characteristic structural metamorphoses in the dental pulp are not dependent on an inflammatory condition, but are referable directly to an altered metabolism or to constitutional changes due to diet. In the complete "pulpar fibrosis" of Zilva and Wells, "no trace of cellular organization, no trace of cell nuclei, no trace of interstitial cement substances can be found anywhere. Nerves, cells, blood vessels and odontoblasts have all shared the process of fibrification and are no longer recognizable. The fine cellular connective tissue, which is but a loose mass of network in the normal state, has either become grossly hypertrophied or quite obliterated, and its place taken by a new firm, fibrous structure, devoid of cells, nuclei, or any regular arrangement of constituted parts." In a scurvy tooth, the condition persists right up to the apex of the root; the change appears to start first in the odontoblastic cells at the top of the pulp, working down toward the apex, followed by distended blood vessels and hemorrhage; then complete fibroid degeneration follows.

If we may believe the new evidence, which deserves a respectful hearing, the teeth are among the parts of the organism first affected by scorbutic causes. Damage may be detected in the teeth before any other symptoms are discovered. For this reason it is not at all unlikely that tooth defects arise owing to faulty diets that are not clearly recognized beforehand. Zilva and Wells remind us of the contention of Hess⁶ of New York that children not infrequently suffer from a "latent scurvy" which is a state of malnutrition that can be diagnosed only by the improvement in the state after the administration of an antiscorbutic. If such unrecognized conditions are widely prevalent, they may help to elucidate the hitherto unexplained prevalence of tooth decay, and they furnish an added argument for renewed efforts to make human dietaries as wholesome as our scientific knowledge, supplemented by food instincts, will permit.

Current Comment

THE ETHICS OF MEDICAL ADVERTISING

What is there about medical advertising, or advertising having a medical or quasimedical slant, that so often causes the advertisement copy-writer to abandon those principles of honesty and common sense which govern the advertising of most meritorious products? Products which are sufficiently good to stand on their own merits and which, when advertised in a nonmedical way, are described truthfully and with not more than the permissible amount of exaggerated puffery that goes with all advertising, are, when they enter the medical or quasimedical field, presented to the public in such a way as to cast discredit on the whole field of advertising. These thoughts are provoked by an advertisement that has recently appeared in certain medical journals on "Adams Chewing Gum." The product itself is one that certainly needs no mis-statements or quibbling to stimulate its sale. The advertisement in question is entitled, "The Care of the Mouth," and is made up largely of what purports to be a quotation from an article by a pediatrician. There are two things wrong with the advertisement. First, the reader is given the impression that the quoted article has appeared comparatively recently; it appeared about eight years ago. Second, the quotation has been garbled and the writer is made to say things that he never said. The parallel indicates the liberties that have been taken:

ORIGINAL ARTICLE

"The child naturally rebels against the cleansing process while it is very ill and therefore if some more attractive and efficient way can be found to accomplish the same result, we ought to take advantage of it. The use of chewing gum seems to offer the best relief. It is attractive to the child . . ." etc.

AS QUOTED IN ADVERTISEMENT

"A child naturally rebels against mouth cleansing while it is ill or peevish, and therefore if some more attractive and efficient way can be found to accomplish the same result, we ought to take advantage of it. 'ADAMS PEPIN CHewing Gum' seems to offer the best relief. It is attractive to the child . . ." etc.

The portions that fail to coincide have been put in small capitals. Aside, altogether, from the medical aspects of the case; aside from the morality or ethics of the matter, *THE JOURNAL* maintains that the liberties which the Adams Chewing Gum concern had taken with the article have weakened rather than strengthened the "copy." These advertisements were for medical journals. The average physician, in reading the advertisement as it appeared, would immediately have his suspicion aroused. This in itself is bad advertising. The reader, knowing that the average physician does not, in scientific articles appearing in medical journals, generally recommend proprietary products, would jump to the conclusion that, if such an article was written, it probably had a vend origin, or else it was probably written by a man of little repute. The chewing gum concern would have made a stronger appeal had they quoted from the original quotation, and then

added their own comment to the effect that if the profession wanted a chewing gum here was one the manufacturers could recommend. In 1919, as never before, honesty in advertising is the best policy.

RELATION OF OPEN PNEUMOTHORAX TO THE TREATMENT OF EMPYEMA

The report of the empyema commission at Camp Lee,¹ and the experiences of various camps, emphasize the advantages of the delayed operation in empyema due to hemolytic streptococci. It will be recalled that the empyema following streptococcus pneumonia differs from the empyema after lobar pneumonia. In the former the fluid forms coincidentally with the pneumonia, the pneumonic process and the toxemia being the most important features, and the pleuritis seemingly of secondary importance. The patients are intensely cyanotic and toxic, often presenting the picture of impending asphyxia. The advantage that has been claimed for the early operation was drainage, which accomplished the removal of both toxic material and living organisms, and in addition relief of the mechanical embarrassment to respiration caused by the presence of a large amount of fluid. Graham and Bell² have made important and interesting experiments on animals and on the human cadaver, the results of which seem to prove, however, that the mechanical embarrassment to respiration is almost sure to be aggravated, instead of improved, by the creation of an open pneumothorax. These investigators call attention to important relationships between the amount of air entering the thoracic opening and the amount of air entering the lungs. If an opening is made into the chest cavity, part of the total amount of air which enters the chest will enter by the opening in the chest wall; but of course only the air which enters through the trachea is effective in carrying on respiration. Thus it comes about that to prevent asphyxia, respiration must be increased in rate of depth; and the greater the opening in the chest cavity, the greater will be the demand for compensation in respiratory rate or depth. It must be remembered that in pneumonia the amount of air taken into the lungs is limited already by consolidation or plugging of the air channels and alveoli; hence the demand for air is increased still more as the opening in the chest further diminishes the amount of air going into the lungs, and the degree of asphyxia already present is increased. Graham and Bell state that "a normal human adult should be capable of withstanding for a short time an opening of 51.5 sq. cm. (5 by 10 cm., or 2 by 4 1/4 inches); but whenever the amount of air taken in the lungs is limited by the presence of an active pneumonia, the size of the pleural opening compatible with life becomes smaller." They believe also that the present conceptions of pneumothorax are erroneous in that they are based on the assumption that when an opening is made in the chest one lung is

1. The Empyema Commission. Cases of Empyema at Camp Lee, A. J. P. 1919, 1920, J. A. M. A. 74:366 (Aug. 31) 443 (Aug. 31) 445.

2. Graham, J. A., and Bell, R. D.: Open Pneumothorax: Its Relation to the Treatment of Empyema, Am. J. M. Sc. 156:839 (Dec.) 1918.

collapsed, an assumption which implies that the mediastinum constitutes a rigid partition between the two pleural cavities. On the contrary, they find in their experiments that the mediastinum is so mobile that any increase of pressure in one pleural cavity pushes it over to the opposite side, so that the two lungs are compressed equally. No such condition is possible, therefore, as collapse of one lung and maintenance of respiration with the other lung in a chest with a normal mediastinum. If, on the other hand, the mediastinum has been made rigid by induration as a result of long standing inflammation, or if it has become fixed by adhesions, then a pleural opening will not produce the same pressure changes on the two sides. The advantages of the delayed operation in empyema are made more evident in the light of these observations on the physiologic mechanics of the thorax. Graham and Bell thus summarize these advantages: 1. There is less danger of creating an open pneumothorax in the delayed operation because there is likely to be a circumscribed abscess shut off by adhesions from any communication with the free pleural cavity. 2. Even if an open pneumothorax is created, the patient is in much better condition to withstand its harmful effect because (a) the subsidence of the active pneumonia has the effect of making the area of air inlet to the lungs larger than when the lung parenchyma is involved in the pneumonia process, so that the pleural opening is incapable of producing the same amount of harm; (b) the presence of adhesions and induration of the mediastinum tend to make it less mobile; (c) the patient's need of oxygen is less, and (d) the respiratory compensation is more efficient, owing to a diminished toxemia. 3. The patient is in a better condition to withstand the shock of the operation. 4. There is less danger of creating a septicemia from the absorption of organisms from the fresh wound. Finally, the fluid can be withdrawn early by aspiration as often as it accumulates in any considerable amount, thus removing the toxic material and organisms without endangering the patient.

“CINCHOPHEN”: FORMERLY “ATOPHAN”

It will be remembered that the Federal Trade Commission adopted the names arspenamin and neosarsphenamin for the drugs first introduced as “salvarsan” and “neosalvarsan,” respectively; the terms barbitol and barbitol sodium for the substances first introduced as “veronal” and “veronal sodium,” and the word procain as the name for the compound first marketed as “novocain.” In issuing licenses for the use of the patents on these drugs, the commission stipulated that the drugs should be sold under the new American title unless the firm desired to use a new trade designation, in which case the titles chosen by the commission should be given equal prominence. The Council on Pharmacy and Chemistry has cooperated with the Federal Trade Commission and has adopted the new names as the descriptive names which appear in New and Nonofficial Remedies. The Chemical Foundation, Inc., which has purchased some 4,500 German-owned patents, many of them for

synthetic drugs, proposes to continue the wise policy of the Federal Trade Commission by requiring that those who receive licenses for the use of patents for synthetic drugs must use a common designation for each drug selected by the foundation. “Cinchophen” has been selected as the designation for the substance introduced as “atophan” (also described in the U. S. Pharmacopoeia under “phenylcinchoninic acid”). In consideration of this action on the part of the Chemical Foundation, and also because physicians found it difficult to use the pharmacopoeial name “phenylcinchoninic acid,” the Council on Pharmacy and Chemistry has recognized the contracted term “cinchophen” as a name for the drug introduced as “atophan.” It is hoped that physicians will support this simplified and nonproprietary nomenclature in the same spirit with which they adopted the terms “arsphenamin,” “barbitol” and “procain.”

OILY OPPORTUNITIES

The following note was received from a physician in New York City:

I received the enclosed letter yesterday and think it deserves publicity. It seems to me, that physicians should be warned against buying Oil Stock at this time, from people whom they know nothing about. Particularly from one whose business should be to take care of the sick and not trying to make easy money out of other physicians. I know enough about Oil Stock products to know that 99 per cent. of them are fakes.

The enclosure referred to was a printed letter in imitation typewriting, signed by, and on the stationery of a physician in southern Texas. The physician in question described himself as “just a plain old doctor” (our records show that he was born in 1881) who had been “wrestling with disease for the past twelve years” (our records show that he was graduated and licensed in 1910). He was, so the letter stated, “personally interested in doctors and their success” and, while he had “made some money” in a “big practice,” he had made much more money during the past six months by “investment” than he had ever made out of the practice of medicine. When the oil field business of Texas began to boom, it occurred to this physician, so he says, that “we Texas people had just as well . . . get our share of all that money as leave it all for the northern and eastern capitalists.” This hardly explains why the doctor is offering a fellow practitioner two thousand miles away in the northeast part of the country a chance to get in on the ground floor. There is, of course, only “a small amount of our stock for sale,” and the physician would “personally like to see some of my doctor friends come in on this.” A postscript to the letter adds that the territory which the Texas doctor is developing is just between a well that is “making 300 barrels at top of sand,” and the place “where the big wells flow.” The doctor hopes, “fraternally,” that the physician to whom he is addressing this printed letter, will “decide to come in.” He is certain that “there is something doing in the oil business”—and we are inclined to agree with him. THE JOURNAL does not undertake to say that the possibilities offered are good, bad or indifferent. Certain it is, however, that however good a gamble the matter may be,

it is a mighty poor investment. When strangers are offered an entrance on the ground floor, it is always wise for them to watch their step—the cellar door may be yawning.

RECOGNITION BY LABOR OF VALUE OF SCIENTIFIC RESEARCH

During these days of unrest the casual observer, as well as the trained student of sociology, may feel that the demands for higher standards of living by industrial workers have wholly overshadowed all attempts at progress in scientific or other endeavor. The passing of a resolution by the American Federation of Labor at its Atlantic City convention, recognizing the ultimate dependence of labor on scientific research, as noted in our News Department several weeks ago, is a hopeful sign. It furnishes evidence that the American Federation of Labor realizes that progress made in raising the standard of living by methods of readjustment is, of necessity, limited, and that in order to pass this naturally prescribed limit the results of scientific research must be applied to industry. The praise indirectly bestowed on the activities of the various governmental branches of scientific research in the preambles to the resolution¹ is well merited. In Great Britain special research commissions have been concerned with scientific studies of hours of labor in relation to health; of the effects of factory work on the health of protective mothers; of infant welfare; of pure food and milk supplies, and even of such detailed matters as the securing of proper vitamin content in food. Already in this country interesting and important researches have developed knowledge relative to fatigue and production; to the mental effects of

prolonged work; to the lighting of industrial establishments, and particularly to such subjects as fire and accident prevention. With strict science as a basis industrial and sociological progress will be well founded.

THE SEARCH FOR "CICATRIZING SUBSTANCES"

The application of accurate methods of measurement, of quantitative procedures, in any branch of science marks a step in the direction of progress. This has been quite as true in medicine as in other fields, such as physics and chemistry. Eye defects are corrected through accurate measurement; metabolic upsets are ascertained through urinary analysis; gastric disturbances are diagnosed through the quantitative examination of stomach contents; febrile symptoms are ascertained by thermometric readings, and blood pressure is evaluated with the help of a manometer. Perhaps these few illustrations will suffice to dispel the impression of uniqueness which may be generated by the application of mathematical laws and formulas to the problems of healing wounds. This procedure has been introduced by Carrel and his associates¹ in their war-time studies of wound healing. The technic involves the accurate measurement of the area of the wounds, to which sterilized cellophane is applied for this purpose, the edges being outlined with a pencil. The area of the drawing can then be ascertained. According to Carrel, cicatrization of a wound is due to two different factors: contraction and epithelization, the former being the more important. Du Noüy² maintains that when the wound is kept aseptic, its rate of cicatrization can be represented by a geometric curve and expressed mathematically. One variable is the age of the patient. Given the latter and the area of the wound, so we are told, one can forecast the rate of normal healing. Aside from its prognostic value, the quantitative study of wound areas has made it possible to ascertain the possible usefulness or harm of various antiseptics which the war has brought forth in large numbers for trial. Most of them are reported to be irritating and more or less detrimental to the normal progress of cicatrization. Du Noüy² now asserts that no such product as a "cicatrizing substance" has yet been discovered. The ideal conditions of perfect and most rapid healing is realized, he states, when the wound is kept practically sterile, or deprived of pathogenic micro-organisms such as cocci, diplococci and streptococci.

1. We reprint here the resolution, including the preambles, which were omitted in previous publication.

WHEREAS: Scientific research and the technical application of results of research form a fundamental basis upon which the development of our industries, manufacturing, agriculture, mining, and others must rest, and

WHEREAS: The productivity of industry is greatly increased by the technical application of the results of scientific research in physics, chemistry, biology, and geology, in engineering and agriculture, and in the related sciences; and the health and well-being not only of the workers but of the whole population as well, are dependent upon advances in medicine and sanitation; so that the value of scientific advancement to the welfare of the nation is many times greater than the cost of the necessary research; and

WHEREAS: The increased productivity of industry resulting from scientific research is a most potent factor in the ever more stringent demands made upon the workers to raise their standards of living, and the importance of such research must steadily increase since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of readjustment, which limit can only be raised by research and the utilization of the results of research in industry;

RESOLVED: That there are numerous important and pressing problems of administration and regulation now faced by federal, state, and local governments, the wise solution of which depends upon scientific and technical research; and

WHEREAS: The war has brought home to all the nations engaged in it the overwhelming importance of science and technology to national defense, whether in time of war or in peace, and not only as private initiative but as a source for leading research in these fields on a national basis; and in view of the increasing governmental participation and support of scientific undertakings already active; therefore, be it

Resolved, by the American Federation of Labor in convention assembled, that a broad program of scientific and technical research is of the utmost importance to the national welfare and should be fostered and encouraged by the federal government, and that the activities of the government itself in such research should be adequately and intelligently supported in order that the work may be greatly strengthened and extended; and the Secretary of the Federation is instructed to prepare a copy of this resolution to the President of the United States, to the President pro tempore of the Senate, and to the Speaker of the House of Representatives.

Aviation and Altitude.—Fifteen to 20 per cent. of all the men who pass an ordinary medical examination are unfit to ascend to the altitudes now required of the military aviator. On the other hand, these tests pick out a small group of 5 to 10 per cent. who, without apparent immediate physical deterioration, withstand oxygen deficiency corresponding to altitudes of 20,000 feet or more. Henderson, Science, July 9, 1919.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending August 1, there were 10,431 officers in the Medical Corps, a decrease of 634 from the previous week. The Medical Reserve Corps contained 3,987 officers. The total number of physicians discharged since the beginning of the war is 22,448.

General and Base Hospitals

On July 15 there were thirty army general and base hospitals operating. Some of these had already been given a definite date for closing. The following tabulation indicates the location of the hospitals and the approximate date when closed:

1. G. H. Plattsburg, N. Y.
2. G. H. Fort Ontario, N. Y., August 1.
3. G. H. Fort Porter, N. Y.
4. G. H. Onusville, N. Y.
5. G. H. New Haven, Conn., September 1.
6. G. H. Fox Hills, N. Y.
7. G. H. Colonia, N. J.
8. G. H. Cape May, N. J., July 20.
9. G. H. Carlisle, Pa.
10. G. H. Fort McHenry, Md.
11. G. H. Takoma Park, D. C.
12. G. H. Hampton, Va.
13. G. H. Roland Park, Md.
14. G. H. Otene, N. C.
15. G. H. Biltmore, N. C.
16. G. H. Spartanburg, S. C.
17. G. H. Fort McPherson, Ga.
18. G. H. Detroit, August 1.
19. G. H. Fort Benjamin Harrison, Ind.
20. G. H. Fort Sheridan, Ill.
21. G. H. Fort Snelling, Minn., August 1.
22. G. H. Fort Des Moines, Iowa.
23. G. H. Hot Springs, Ark.
24. G. H. Denver, Colo.
25. G. H. Fort Bayard, N. M.
26. G. H. Whipple Barracks, Ariz.
27. G. H. Fort Douglas, Utah, August 1.
28. G. H. San Francisco.
29. R. H. Fort Riley, Kan.
30. B. H. Fort Sam Houston, Texas.

General hospitals at Parkview, Pa., and Eastview, N. Y., were closed July 15. Base hospitals at the following camps, not shown above, are scheduled to be made camp hospitals: Bowie, Texas; Devens, Mass.; Dix, N. J.; Dodge, Iowa; Gordon, Ga.; Grant, Ill.; Jackson, S. C.; Lee, Va.; Lewis, Wash.; Meade, Md.; Pike, Ark.; Shelly, Miss.; Sherman, Ohio; Taylor, Ky.; Union, L. I., N. Y.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Surg. W. C. BILLINGS, proceed to Boston, Mass., stopping at Washington, en route, for conference for the study of hospital equipment and administration.

Surg. W. A. KORN, proceed to White Barracks, Arizona, for instruction relative to the initial duty for Public Health Service Hospital.

Surg. JOHN T. DEBKHALTER, proceed to Anviston, Ala., for instruction relative to suitability for Public Health Service Hospital.

Surg. R. E. EBERSOLE, relieved at Ellis Island, N. Y., proceed to New Orleans, La., and assume charge of the Marine Hospital.

Passed Asst. Surg. ROBERT OLESON, proceed to Madison, Wis., to assist the State Health Officer in establishing an endemic index for the reportable diseases.

Passed Asst. Surg. C. L. WILLIAMS, proceed to New Orleans, La., to assist the State Health Officer in establishing an endemic index for the reportable diseases.

Passed Asst. Surg. W. L. TREADWAY, proceed to New York, to deliver two addresses at Teachers' College, Columbia University.

Passed Asst. Surg. A. R. SWEENEY, relieved at Fayetteville, N. C., proceed to the Marine Hospital, Stapleton, N. Y., for duty.

Passed Asst. Surg. C. V. AKIN, designated as epidemiologic aide to the health officer for the State of South Carolina to assist in establishing an endemic index for the reportable diseases.

Asst. Surg. W. S. DEAN, relieved from duty at the Bureau, Washington, D. C., proceed to Atlanta, Ga., to assist the State Health Officer in establishing an endemic index for the reportable diseases.

Asst. Surg. VANCE B. MURRAY, relieved at the Marine Hospital, San Francisco, Calif., proceed to Manila, P. I., and report to the Chief Quarantine Officer for duty.

Asst. Surg. CHARLES ARMSTRONG, proceed to Columbus, Ohio, to assist the State Health Officer in establishing an endemic index for the reportable diseases.

Asst. Surg. R. E. DYER, proceed to Little Rock, Ark., to assist the State Health Officer in establishing an endemic index for the reportable diseases.

Asst. Surg. M. V. ZIEGLER, proceed to Indianapolis, Ind., to assist the State Health Officer in establishing an endemic index for the reportable diseases.

Passed Asst. Surg. C. R. MILLER (Reserve), ordered to active duty in the Reserve Corps of the U. S. Public Health Service. Proceed to Greenville, S. C., for duty.

Asst. Surg. RICARDO MESTRE (Reserve), ordered to active duty in the Reserve Corps of the Public Health Service. Proceed to Leavenworth, Mass., for duty under the Supervisor District No. 1.

Asst. Surg. FESSENDON N. OTIS (Reserve), ordered to active duty in the Reserve Corps of the Public Health Service. Proceed to the Marine Hospital, Boston, Mass., for duty.

Act. Asst. Surg. A. M. GANAWAY, proceed to St. Louis, Mo., and report to the Marine Hospital for duty.

Act. Asst. Surg. GEORGE HAYES, proceed to Nashville, Tenn., for duty in venereal disease control.

Act. Asst. Surg. D. B. HOLLOWAY, relieved at Newport News, Va., proceed to the Marine Hospital, Cleveland, Ohio, for duty.

Act. Asst. Surg. A. J. HOSKINS, proceed to Palo Alto, Calif., for duty in the Public Health Service Hospital.

Act. Asst. Surg. A. M. KILGORE, proceed to the Marine Hospital, New Orleans, La., for duty.

Act. Asst. Surg. STAFFORD B. SMITH, proceed to the states of New York, New Jersey, Pennsylvania for conference with Health Officers relative to venereal disease control.

Act. Asst. Surg. W. H. WALSH, proceed to Cape May, N. J., for inspection of Naval Hospital, relative to its suitability for use by the Public Health Service.

Influenza Deaths.—The *Weekly Health Index* for March 4, 1919, issued by the Bureau of the Census, shows that in thirty-one of the larger cities of the United States with a population of over 192½ million for the period of twenty-five weeks from Sept. 8, 1918, to March 1, 1919, inclusive, there were 72,009 deaths from influenza and 49,598 from pneumonia in all forms, giving, for the two diseases, a rate of 6.2 per thousand of population. There was said to be an excess of deaths from all causes of 96,679, or 5.0 per thousand of population as compared with the deaths and death rate for 1919.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

Medical Museum Secures Collection of Microscopes.—A large and quite complete collection of microscopes has been assembled at the United States Army Medical Museum, constituting an important addition to the exhibits of that valuable institution. Specimens are included from the crude models of centuries ago to the most modern and powerful of the compound microscopes of today.

Changes in Health Department Personnel.—Dr. John L. Norris, recently captain, Medical Corps, U. S. Army, has resumed his post as assistant health officer, the acting assistant health officer, Dr. John Paul Frey, having been appointed chief of the contagious disease service, vice Dr. Harry S. Bernton, resigned. Dr. Bernton is in charge of the medical work of the Washington Diet Kitchen Association.

Compensation for School Medical and Dental Inspectors.—The recent appropriation act for the District of Columbia failed to include the requested increased compensation for medical and dental inspectors, the basic salary still remaining \$500 per annum, the sum fixed in 1903 when medical inspection of schools was first inaugurated. These inspectors will receive, however, the bonus of \$240 provided for all federal and district employees receiving basic salaries of \$2,000 or less. The chief medical inspector of schools was allowed maintenance for a motor vehicle.

Plans for Medical Society Building Approved.—Plans and specifications for the proposed home for the Medical Society of the District of Columbia have advanced to a point permitting expectations that bids will be invited early in September. The plans of the building have been submitted to the National Commission of Fine Arts and have received the complete approbation of that body. At a recent meeting of the building committee further progress in raising funds was announced. Generous contributions from the lay public have been received. Dr. Lawrence M. Hynson was elected secretary of the committee, succeeding Dr. Hanson T. A. Lemon, deceased.

Personal.—Lieut.-Col. Charles A. Ragen, M. C., U. S. Army, retired, has removed to New York City where he intends to practice medicine.—Dr. Daniel Webster Prentiss has recently returned from France where he was in charge of the surgical service at Base Hospital No. 106, Beau Desert hospital center, near Bordeaux.—Dr. Francis P. Morgan has resumed his work in the bureau of chemistry, Department of Agriculture, having recently returned from service in France with the A. E. F.—Among those recently returned from military to civilian activities are Major A. Barnes Hoce, Lieut.-Col. Luther H. Reichelderfer, Major Walter A. Wells, Major Henry F. Sawtelle and Capt. Howard Hume.

ILLINOIS

Medicine Man Fined.—J. W. Garrett, a colored medicine man of East St. Louis, is said to have been found guilty, July 19, of having violated the medical practice act, and to have been fined \$100.

Deaths of 1918.—During 1918, 103,130 persons died in Illinois and of these, 44,605 were residents of Chicago. The death rate for the state was 16.3 per thousand population. The increase in the death rate is due to the influenza-pneumonia pandemic from which 32,334 persons died.

County Officers Re-elected.—At the annual meeting of the Ogle County Medical Association, held at Rochelle, July 21, the following officers were re-elected: president, Dr. Walter E. Kittler, Rochelle; vice president, Dr. Jesse C. Akins, Forreston, and secretary-treasurer, Dr. Josiah T. Kretsinger, Leaf River.

Hospital Items.—Plans have been drawn for the Tazewell County Sanatorium for Tuberculosis which is to be erected on a site recently purchased in Mackinaw. The building is to cost about \$45,000.—A drive has been started at LaSalle to raise \$40,000 with which to build an addition to St. Mary's Hospital.—Miss Grace Welch, Millburn, has

been appointed superintendent of Jane McAllister Hospital, Waukegan.

Sanatorium for Piatt County.—Mr. Robert Allerton of Chicago, July 30, offered to sell 1,200 acres of land and donate the proceeds to Piatt County if the supervisors would use the amount for the erection of a tuberculosis sanatorium. This offer, amounting to a donation of about \$400,000, was offered by Mr. Allerton as a memorial to his father, the late Samuel W. Allerton of Chicago, and his friend, the late John Phalen. The gift was formally accepted by the supervisors of Piatt County, August 2.

Illegal Practitioner Arrested.—Dr. H. R. Orbid, "the Eminent Dr. Orbid of Ohio," was arrested by the Illinois Department of Registration and Education for practicing medicine at Joliet without a license and was committed to jail until he secured a bondsman. As soon as he was released he departed for parts unknown and did not appear for the trial. Dr. Orbid was fined \$200 and costs, of which his bondsman paid \$100 and will be required to pay the remaining \$100 if he cannot locate Orbid and present him in court. It was found that Orbid had in his possession an army officer's uniform with a variety of insignia so that he could assume any rank he desired. There is nothing to indicate that he was ever in the service.

Chicago

Postgraduate Nursing Course.—A postgraduate course of training in nursing is being held at the Illinois Training School for Nurses. The course lasts six weeks, with eight hours work each day for five days a week, and is being taken by eighteen women who hold executive positions in hospitals. Among the subjects are curriculum, planning of hospitals and nurses' residence, ethics of nursing and psychology.

Personal.—P. J. H. Farrell, Lieut.-Col., M. C., U. S. Army, and in command of Base Hospitals Nos. 81 and 81a, A. E. F., France, returned to Chicago, August 4.—Dr. Sophia Brumback has been appointed a member of the morals commission, succeeding Dr. Anna Dwyer.—Radium valued at \$3,000 disappeared from the office of Dr. Frank E. Simpson, July 25. He has offered a reward of \$500 for the return of the radium.

Site Bought by State.—A new hospital to be known as the State Surgical Institute for Children is to be built on the site of the baseball park at Lincoln and Polk streets. There will be three other hospitals on this site, the Illinois Charitable Eye and Ear Infirmary, a clinic for students of the Medical College of the University of Illinois, and the State Psychopathic Hospital. The land has already been bought for \$400,000 and more than \$1,500,000 has been appropriated to begin the construction of the hospital group.

Training School for Public Health Nursing.—More than 600 women registered, August 2, for the new course offered by the Chicago Training School for home and public health nursing. Five courses are offered by the school which opened, August 4, in the building formerly occupied by the Loyola Medical School on West Fulton Street. The board of directors for the institution includes, the Mayor, Mrs. Edward Hines, William A. Fetzner, Dr. William A. Evans, the Rev. Samuel Fallows, D. F. Kelley, Simon O'Donnell, and Miss Annie McKenzie, R.N. The Chicago Chapter of the American Red Cross has appropriated \$15,000 to meet the expense of these courses.

INDIANA

Health Association Reorganized.—At a meeting recently held at Cedar Lake, the Lake County Health Association was reorganized and the following officers were elected: president, Dr. Otis B. Nesbit, Gary; vice presidents, Mr. G. Miller, East Chicago, and Dr. Eli S. Jones, Hammond, and secretary-treasurer, Mr. K. E. Hall, East Chicago.

Physician Reinstated.—In the case of Dr. George F. Smith, Bicknell, whose license was revoked by the State Board of Medical Registration and Examination, February 27, for alleged misrepresentation in regard to high school credits, an official order of reinstatement has been filed by the board with the clerk of Knox County as the result of an appeal made by Dr. Smith to the Knox Circuit Court.

Personal.—Dr. John N. Hurty, state health commissioner, is ill at his home in Indianapolis.—Dr. Clarence K. Jones has been appointed an alternate on the gynecologic staff of the Indianapolis City Hospital, and Dr. John W. Carmack has been appointed an alternate on the ear, nose and throat staff.—Dr. C. E. Edmondson, Bloomington, has been made

head-of-the new department of hygiene in the Indiana University.

Alleged Violation of Liquor Law.—Dr. Alonzo S. Neely, Indianapolis, is said to have been indicted by the Marion County Grand Jury for violation of the prohibition law on two counts, the first charged the physician with having sold liquor to persons unknown to the grand jury and the second, with having had whisky in his possession unlawfully. —Dr. George Kouns, Indianapolis, who was recently convicted in the city court on the charge of having provided morphin for a woman addicted to the drug habit, was tried before the Indiana State Board of Registration and Examination, July 8, on another similar charge.

IOWA

New Officers.—The Austin Flint-Cedar Valley Medical Society held its annual mid-summer meeting at Clear Lake, July 8 and 9. Dr. Oren M. Landon, New Hampton, was elected president; Dr. Albin B. Phillips, Clear Lake, vice president, and Dr. William A. Kohn, Waverly, secretary.

Personal.—Dr. George F. Severs, Centerville, has been appointed president of the state board of health succeeding Dr. Walter L. Biering, Des Moines. —Dr. Ralph W. Mendelson, Des Moines, is being sent by the Siamese government to have charge of the campaign against cholera in northern Siam.

MARYLAND

Personal.—George Milton Linthicum, Lieut.-Col., M. C., U. S. Army, Baltimore, who served overseas with Base Hospital No. 113, has returned to the United States.

Marine Hospital to Expand.—To relieve the congestion at the Marine Hospital, a new psychiatric ward of thirty beds will be erected within the next two months. It will be a one story building of temporary construction. The hospital is now filled to capacity, with 150 patients, which includes men who have been gassed or wounded overseas.

Government to Run Quarantine Station.—Baltimore city has again entered into contract for a lease of the quarantine station by the government at \$1 a year, until Congress makes an appropriation for the grounds and buildings. Suggestions from Health Commissioner Blake that the main office of the station be moved to Fort McHenry or elsewhere in the city, and that a quarantine boat be maintained at the Fort McHenry wharf have been accepted by the government. This will reduce the cost of operating the station and will do away with one or more boat crews.

Infantile Paralysis and Typhoid.—Infantile paralysis has again appeared in Baltimore during the past week, four cases and two fatalities having been reported to the health department. The cases were confined to children and Dr. John F. Hogan, Baltimore, chief of the bureau of communicable diseases, did not consider the situation one to cause alarm. What the officials of the department regarded with more concern were eighteen cases of typhoid from Baltimore, four of which came from the new Annex. Investigation has shown that several cases could be traced to outside infections. All the cases are under investigation. Fourteen cases of typhoid fever at Bakersville were reported to the state department of health by the Washington County Health Board. Samples of water taken from ten wells at Bakersville and vicinity have been sent to the health department for analysis. So far there have been no deaths from typhoid at Bakersville.

Permanent Exhibit at Fort McHenry. With the assurance that U. S. Army General Hospital No. 2, at Fort McHenry, will be retained as a hospital for the treatment of wounded and diseased soldiers for at least a year longer, the officials there are planning to install a permanent exhibit of the surgical work and to have special days each week for visitors. Col. James H. McHenry, New York City, chief of the general surgical work, is anxious that this permanent exhibit of the treatment and cures among the wounded soldiers be shown at the hospital until the post is surrendered. Col. McHenry with Colonel McHenry and the other officers are present at the Johns Hopkins Hospital and the University of Maryland who are convinced that this demonstration would be invaluable to the medical students of the two institutions. The permanent exhibit will be along the lines of the one which attracted such favorable attention at the Medical and Chirurgical Faculty Building, but will be more comprehensive. The physicians at the post have achieved an excellent record in operations. Out of 400 patients operated on since last January, only one death directly attributable to an operation has occurred.

MINNESOTA

Public Health Associations Organized.—Thus far, auxiliaries of the Minnesota Public Health Association have been organized in eighty of the eighty-six counties of Minnesota.

New Officers.—At the fifty-fifth annual meeting of the Wabasha County Medical Society, held at Lake City, July 10, Dr. Jesse A. Slocumb, Plainview, was elected president; Dr. John T. Bowers, Lake City, vice president, and Dr. William F. Wilson, Lake City, secretary-treasurer. The next meeting of the association will be held at Zumbro Falls.

Personal.—Dr. Charles E. Smith, Jr., St. Paul, has assumed the duties of executive officer of the state board of health, succeeding Dr. Henry M. Bracken, resigned. Dr. Bracken is devoting his time to war risk insurance in connection with the United States Public Health Service. —Kenneth Taylor, Col., M. C., U. S. Army, St. Paul, has returned from France. —Dr. Oscar W. Holcomb, St. Paul, and Axel E. Hedback, Minneapolis, have been appointed members of the state board of health, succeeding Drs. Christopher Graham, Rochester, and Werner Hemstead, St. Cloud.

Supervision of Public Health Nurses.—Arrangements have been completed between the American Red Cross and the Minnesota Public Health Association which give the former organization supervision over, and responsibility for, public health nursing in Minnesota. The basic agreement is that the American Red Cross is to secure and place all permanent public health nurses, and help finance them and supervise them. This does not include demonstration nurses or hospital or sanatorium nurses. The association is to conduct public health educational, propagandist and legislative activities and to cooperate with the American Red Cross in all directions regarding public health, but is not to finance county or community public health nurses.

MISSISSIPPI

Colored Practitioners Meet.—At the meeting of the Mississippi Medical and Surgical Association (colored) held in Jackson, July 9, Dr. Daniel W. Sherrod, Meridian, was elected president; Dr. John H. Roby, Canton, vice president, and Dr. Robert L. Johnson, Jackson, secretary.

Hospital Items.—An attempt is being made to secure a bond issue of \$8,000 from the city of Meridian with which to purchase the Matty Hersee Charity Hospital property and erect thereon a new modern hospital. At present the institution is being operated by the appropriation of \$11,000 per year from the state and \$5,000 from Meridian and \$2,000 from Landerdale County. —The board of trustees of the South Mississippi Charity Hospital, Ellisville, has petitioned the governor to call an extra session of the legislature to provide additional funds for the support of a hospital. —Officers of the Biloxi Hospital Association have started a drive for funds for the erection of a new modern hospital building for Biloxi. —A campaign has been opened to secure \$250,000 for the Baptist Hospital, Jackson.

Personal.—Dr. C. D. Alexander, Vaiden, has been appointed health officer of Carroll County. —Dr. Robert B. Crisler, Sartoria, sustained a severe injury to his arm recently when his automobile backfired. —Dr. Taylor H. Henry, Columbus, has been re-elected health officer for Lowndes County. —Dr. Sylvan Myers, Vicksburg, has been elected health officer of Warren County. —Dr. Daniel J. Williams, Gulfport, has been re-elected health officer for Harrison County. —Dr. J. B. Middleton, Grenada, has been reappointed health officer for Grenada County. —Dr. William A. Carpenter, Meridian, has been reappointed health officer of Landerdale County. —Dr. Thomas R. W. Wilson, Greenville, S. C., who has been in charge of the base hospital, Camp Shelby, has been made director of the hygienic laboratory of the state department of health, Jackson.

MONTANA

Hospital Training Institute. The Second Montana Institute for Hospital Training in connection with the University of Montana was held at Missoula, from June 30 to July 12, under the charge of Prof. W. G. Bauman of the department of chemistry of the university.

Personal. Dr. Ernest D. Hieschek has been appointed state bacteriologist of Montana, succeeding the late Dr. Arthur H. McCray, Helena, and has assumed charge of the laboratory. The widow of Dr. McCray has been appointed superintendent of public health nurses in Montana.

Public Health Association Organized.—At the final session at the conference of the state health board, held in Butte, July 9, the Montana Public Health Association was organized and the following officers were elected: president, Prof. W. M. Colleigh, Bozeman; vice president, Dr. Harmon T. Rhodes, Choteau; secretary, Dr. William F. Cogswell, Helena; treasurer, Dr. Wilson A. Russell, Hardin, and section heads, Dr. Louis W. Allard, Billings, public health administration; Dr. Caroline McGill, Butte, tuberculosis; Surveyor General Gerhart, Helena, sanitation and water works; Mrs. Harry B. Farnsworth, Missoula, child welfare; Dr. Patrick H. McCarthy, Butte, industrial hygiene, and Dr. Eugene G. Steele, Plentywood, health hygiene. The next meeting will be held at the same time and place as the annual convention of the Montana State Medical Association.

New State Officers.—The Montana State Medical Association held its annual meeting in Missoula, July 9 and 10, under the presidency of Dr. Edward W. Spottswood, Missoula. Helena was selected as the next meeting place and the following officers were elected: president, Dr. Edward M. Larson, Great Falls; vice presidents, Drs. Lawrence Stevens, Laurel, Patrick H. McCarthy, Butte, and Arter W. Deal, Lewistown; secretary-treasurer, Elmer G. Balsam, Billings, and delegate to the American Medical Association, Dr. Edward W. Spottswood, Missoula, the retiring president. The association also adopted the report of a committee which submitted the names of the following five members from which the governor will select one to be named as a member of the state board of health: Drs. E. M. Porter, Lewistown; Austin L. Ward, Havre; Arter W. Deal, Lewistown; Mark D. Hoyt, Glasgow, and Edward M. Gans, Judith Gap.

NEW JERSEY

Urge Memorial Hospital.—Women of Gloucester are making a determined effort to have a memorial hospital erected instead of a monument in memory of the 300 soldiers from Gloucester who went into the service. It is believed that they will be able to raise \$25,000 for a hospital.

Drug Crusade Begun.—A crusade against the illegal sale of iodine, paregoric, castor oil and other such medicines by grocery stores and other places which have no license, has been started by the New Jersey State Board of Pharmacists. A tour is being made of each of the South Jersey towns. They claim that no one but a licensed druggist can sell such medicines.

NEW YORK

Combat Against Habit-Forming Drugs.—Federal officials have begun a campaign to stamp out the traffic in habit-forming drugs. In two raids, made July 16, seven persons were arrested, six charged with violation of the Harrison Narcotic Law, and the other, an alleged addict, was held as a material evidence.

Plan Home for Infirm Physicians. The certificate of incorporation of the Physician's Home, among the incorporators of which are Drs. Graeme M. Hammond, Alexander Trautman, Daniel Cook, Max Einhorn, Silas F. Hallock, Robert T. Morris, and Albert G. Weed, all of New York City, was approved by Justice Ford, August 1. The purpose of the organization is to create and maintain a home for aged and infirm physicians and their wives or widows or to assist them in any other way feasible.

Development of Letchworth Village.—July 9, the governor opened and dedicated Stewart Hall, the school and recreation building of Letchworth Village, and laid the cornerstone of the new group of buildings for women. In his address on this occasion the governor stated that there were at least 33,000 mental defectives in the state, of which only 5,000 were properly provided for. Dr. Pearce Bailey, chairman of the State Commission on Feeble-minded, made a strong plea for research into the cause of mental defects and especially urged the establishment of a pathologic laboratory at Letchworth Village.

Drug Law Fails in State.—Reports received from various up-state counties show that the Whitney anti-narcotic law is almost wholly inoperative outside of New York City, because of failure of the legislature which passed the act to appropriate the necessary funds for its administration. The state department of drug control announces that in view of the lack of funds with which to carry out the provisions of the law, it will have to depend on individual physicians to report to the health authorities of the various counties drug addicts encountered in private practice. Thus far it is announced that the health authorities have received practically no

reports from physicians. It is feared that this condition of affairs is likely to result in an illicit traffic in drugs outside of New York City that will render registration in New York City a farce. Albany has a clinic for drug addicts and it is likely that another will be opened in Buffalo.

New York City

Convalescent Home for Soldiers.—A convalescent home for discharged men from overseas suffering from nervous troubles has been opened in Bronxville. The Seabury Society of New York will maintain the home. The home is already filled but as fast as vacancies occur other patients will be received.

Typhoid in New York City.—During the second quarter of 1919, ninety-nine cases of typhoid fever were reported with twenty deaths, as against 268 cases for the corresponding quarter of last year. Of these cases 89 per cent were confirmed by laboratory examination. The source of infection was traced in only 24 per cent of the reported cases.

Health Department Gets Hospital Accommodations for Drug Addicts.—Secretary Daniels of the Navy has granted the use of the buildings at the Pelham Bay Naval Training Station to New York City for the treatment of drug addicts. This will provide accommodations for 1,000 patients within a brief period. The location is regarded as an exceptionally good one because it can be well guarded and secured against the smuggling of drugs which has been one of the difficulties with which the city has had to contend at all other institutions where it has attempted to care for drug addicts.

Many Bogus Diplomas Sold.—Assistant District Attorney DeCoro announces that some one hundred New York "physicians," "dentists" and "druggists" face prosecution in the near future. The man arraigned for having sold these diplomas is Nicholas D. Clements of the Bronx, who, two years ago, was sentenced to two and one-half years in Dannemora prison for having sold talcum powder as aspirin. The diplomas for which Clements received from \$100 to \$150 each purport to be from the Southern Medical Institute, which went out of existence fifteen years ago. Clements asked for clemency in his promise to reveal the names of the seventy-five physicians and attorneys who purchased their credentials from him.

U. S. Public Health Service Takes Polyclinic Hospital.—The Polyclinic Hospital will be taken over by the U. S. Public Health Service, August 15. The institution will be used exclusively for the treatment of war risk insurance cases. The Public Health Service also took over in June, the old Hudson Street Hospital which was used by the Navy for the same purpose. There are accommodations for 450 patients in the Polyclinic and for 120 in the Hudson Street Hospital. Former soldiers who were insured, if ailments develop directly or indirectly from their war experience, will be treated at these hospitals. James L. Robinson, M. C., U. S. Army, is in charge of the Polyclinic and Dr. Richard A. Kearney of the Hudson Street Hospital.

OHIO

Salaries Increased.—The trustees of the Western Reserve University, Cleveland, have voted an increase of 20 per cent to the salaries of the entire full-time instructing staff of the medical school.

Personal.—Frank Winders, Major, M. C., U. S. Army, Columbus, who has been for many months a director of the medical service of the Port of Embarkation, has been promoted to the rank of lieutenant-colonel, Medical Corps. Dr. Edward M. Keefe has been appointed local surgeon for the New York Central system, with headquarters at Cincinnati.

Hospitals Must Register. In compliance with the terms of the law passed by the legislature in March, which went into effect, June 25, every hospital and dispensary in the state must register immediately with the state department of health. The registration and report will serve as a basis for a survey of the hospital facilities of the state. A division of hospitals has been created in the state department of health to look after this survey.

Health Bureau Moved to Columbus. The health activities of the state for the control of venereal disease have been placed on a more efficient basis by the removal of the bureau of venereal disease of the state department of health to the headquarters of the department of health in Columbus. This bureau was established at Cleveland a year and a half ago when the call of the War Department for antivenereal bureaus found the state without funds for the purpose. Dr. Harold

N. Cole, Cleveland, assumed charge of the bureau and served without compensation until federal funds were awarded to the state for carrying out the program. He has now resigned from the bureau but will continue to serve as consultant.

The Hughes Act.—Arrangements are under way in many counties for meetings of the district advisory committees immediately after the law goes into effect, August 9. These councils are composed in each county, of the mayors of all cities under 25,000 population and the chairmen of all township boards of trustees. At the meeting for organization each council will select the district board of health which will appoint a full-time district health commissioner and other employees from a civil service list. Cities of more than 25,000 population will institute separate health districts, with organization similar to that now in force excepting that health officers and other employees will serve on a whole-time basis and will be appointed under civil service rules.

OREGON

Woman's Medical Club Elects Officers.—At the annual meeting of the Portland Woman's Medical Club, June 10, Dr. Jessie M. McGavin was elected president; Dr. Emma J. Wickstrom, vice president; Dr. Ethel Gray, secretary, and Dr. Amelia Ziegler, treasurer.

Alumni Election.—At the seventh annual meeting of the Alumni Association of the University of Oregon Medical Department, Portland, June 24, the following officers were elected: president, Dr. A. A. Whitham, Portland; vice presidents, Drs. Louis Buck, Portland; Carl Hoffman, Woodland, Wash.; Adalbert G. Bettman, Portland, and James L. Wooden, Clatskanie; secretary, Dr. George A. Cathey, Portland, and treasurer, Dr. Katherine Manion, Portland.

New State Officers.—The forty-fifth annual meeting of the Oregon State Medical Association was held in Portland, June 26 to 28, under the presidency of Dr. Charles M. Barbee, Portland, and the following officers were elected: president, Dr. Burpee L. Steeves, Salem; president-elect, Dr. Joseph A. Pettit, Portland; vice presidents, Drs. William R. Neal, Eugene; Charles S. Edwards, Prineville, and Hugh S. Mount, Oregon City; secretary, Dr. Clarence J. McCusker, Portland; treasurer, Dr. Jessie M. McGavin, Portland, and councilors, Drs. Philip J. Bartle, Eugene, and Abram L. Houseworth, Marshfield.

Personal.—Ralph A. Fenton, Major, M. C. U. S. Army, Portland, who has been in charge of eye work in the Army of Occupation, has been relieved from duty with the Third Army and has returned home.—Dr. Elbert E. Cable, Portland, who has been stationed at Newport News, Va., and New York City as government specialist in community sanitation, has returned to Portland and has been appointed medical supervisor of the War Risk Insurance Bureau for the Thirtieth District, which includes the states of Oregon, Washington and Idaho.—Justin M. Waugh, Major, M. C. U. S. Army, Hood River, who recently returned from abroad, has been promoted to the rank of lieutenant colonel, Medical Corps.—Dr. Esther C. Pohl Lowjoy, Portland, has been appointed chairman of the American women's hospitals with headquarters in New York City.

PENNSYLVANIA

Personal. Col. William J. Crookston, Pittsburgh, chief surgeon of the Twenty-Eighth Division in France, has been appointed associate chief medical inspector of the Pennsylvania Department of Health. He will succeed Dr. Howard L. Hull, Camp Hill, who has been appointed chief medical inspector of the Pennsylvania Department of Health. Dr. Edward Martin, commissioner of health, announces the following appointments in his department: Dr. Edward W. Bixby, Wilkes-Barre, and Miriam Wagner, Philadelphia, assistants in the genito-urinary division; Dr. Roy Ellithorp, Kane, Highland Township, Elk County, and Dr. James Allen, Ranchowin, Crawford Township, Clinton County, health officers.

Philadelphia

Little Mothers' Leagues Formed. The Child Federation has been cooperating with the public school playground department of the board of education in forming little mothers' leagues to instruct the children in the care of their baby brothers and sisters. The Little Mothers' Leagues have been established in the public schools and in the Light-house Settlement, Neighborhood Center and Reed Street Settlement. At the playgrounds the classes are taught by the teachers as a regular part of the playground activities, and at the

settlements the classes are in charge of nurses from the division of child hygiene.

To Ask Funds for College.—Plans are afoot for a fund-raising campaign for the Woman's Medical College of Pennsylvania, according to a statement made by Dr. Martha Tracy, dean of the college. The campaign, which will be conducted entirely by women, will open, October 13, and continue until October 23. The Woman's Medical College is the only medical school in the United States which admits women exclusively. The appeal for funds is occasioned by the need for extending and developing the work of the medical college for a new residence hall for nurses and students, and for enlarging and increasing the facilities of the Woman's College Hospital, which is connected with the medical college.

WISCONSIN

Poliomyelitis in Milwaukee.—There have been reported thirty-six cases of infantile paralysis in Milwaukee and all hospitals have set aside beds for the treatment of these cases. The city council has authorized the publication and distribution of pamphlets instructing the people how to prevent contagion and how to deal with the disease.

Personal.—A welcome home banquet was given Dr. Gerhard A. Bading, formerly mayor of Milwaukee, at the Milwaukee Athletic Club, July 15. Dr. Bading has recently returned from the Philippine Islands where he served as captain, M. C. U. S. Army.—Charles H. Stoddard, Major, Wis. N. G., Milwaukee, has been appointed chief surgeon of the state.

State Board Notes.—Dr. Gustave Windesheim, Kenosha, has been appointed a member of the state board of health.—Dr. Cornelius A. Harper, Madison, state health officer, has been reappointed a member of the state board of health.—Drs. George H. Ripley, Kenosha; Henry W. K. Abraham, Appleton; Charles W. Rodecker, Holcombe, and John M. Dodd, Ashland, have been reappointed members of the state board of medical examiners.

Hospital Items.—Drs. S. Wade and John C. Doolittle, Lancaster, have opened their new hospital in the Wright Block.—The Milwaukee County Free Dispensary has been opened at Grand Avenue and Fifth Street, Milwaukee. This is the first unit of the new county hospital which is to be established on the former Schandeen estate.—Fifteen physicians of Oshkosh have purchased an apartment building and have organized the Oshkosh Clinic which has been incorporated by Drs. Clarendin J. Combs, Henry W. Morgenroth and Charles H. Nims.

CANADA

Personal.—Dr. Perry G. Goldsmith, Toronto, lieutenant-colonel in the Canadian Army Medical Corps, has been appointed a Commander of the Order of the British Empire.—Lieut.-Col. Graham Chambers, Toronto, who has been overseas since May, 1915, sailed for home on the *Adriatic*, July 28.

University News.—Principal Bruce Taylor of Queen's University, Kingston, Ont., has reported to the board of trustees that it may be necessary to transfer the clinical work of the medical department to Ottawa, when the new hospital is completed, as the population of Kingston makes the supply necessarily inadequate.

Medical Council of Canada.—The annual session of the Medical Council of Canada was held in Ottawa a short time ago, under the presidency of Dr. Richard Eden Walker, New Westminster, B. C. The Medical Council of British Columbia relinquished their local provincial examination for their license in favor of the examination as set by the Medical Council of Canada. Another matter of importance discussed was the negotiation with Great Britain and other countries looking toward reciprocal acknowledgment of licenses. An amendment to the Canada Medical Act providing for these proposed changes will be drafted and presented to the next annual session of the council. Examinations were ordered to be held in Montreal and Halifax in October, 1919, and in Toronto, Winnipeg and Vancouver in June, 1920. Dr. James C. Connell, Kingston, was elected president.

GENERAL

Smallpox on Board Ship. On the arrival of the troopship *Mobile* at New York, smallpox was discovered on board and more than 5,000 passengers on the ship were placed in temporary quarantine.

Bulletin of the League of Red Cross Societies.—The first two numbers of a new publication the *Bulletin* of the League

of Red Cross Societies published at Geneva, Switzerland, have just been issued. The first number is devoted to the history of the league and its organization, and the second number to the proceedings of the medical conference held at Cannes, France, in April, and already reported in *THE JOURNAL*.

Gastro-Enterologists Elect Officers.—At the annual meeting of the Gastro-Enterologists' Association, held in Atlantic City, N. J., June 9 and 10, the following officers were elected: president, Dr. Thomas R. Brown, Baltimore; vice presidents, Dr. Franklin W. White, Boston, and Joseph Sailer, Philadelphia; secretary, Dr. Frank Smithies, Chicago; treasurer, Dr. Clement R. Jones, Pittsburgh; recorder, Dr. Horace W. Soper, St. Louis, and Councilor, Dr. Walter A. Bastedo, New York City.

Advisory Medical Committee to Children's Bureau.—An advisory medical committee has been appointed to the Hygiene Division of the Children's Bureau, United States Department of Labor. It consists of three members, Dr. Julius Hess, Chicago, representing the Section on Diseases of Children of the American Medical Association; Dr. Richard Smith, Boston, representing the American Pediatric Society, and Dr. Howard Childs Carpenter, Philadelphia, representing the American Child Hygiene Association.

National Tuberculosis Association Elects Officers.—At the annual meeting of the National Tuberculosis Association, held at Atlantic City, N. J., June 15 and 16, the following officers, executive committee members and directors were elected: president, Dr. Victor C. Vaughan, Ann Arbor, Mich.; honorary vice presidents, Sir William Osler and George E. Bushnell, Col., M. C., U. S. Army; vice presidents, Dr. Gerald B. Webb, Colorado Springs, and John M. Glenn; secretary, Dr. Henry Barton Jacobs, Baltimore; treasurer, Henry B. Platt, New York City.

Bequests and Donations.—The following bequests and donations have recently been reported:

Dr. Steven Seymour memorial endowment fund, \$100,000 for the endowment of hospital beds in memory of Dr. Steven Seymour of Chicago by the will of his daughter, Mrs. Katherine E. Brown.

Miler Memorial Hospital, New Orleans, a donation of \$5,000 by Dr. Theolon Quayle.

The Associated Jewish Charities, Chicago, a bequest of \$50,000 by the will of Louis M. Stumer.

St. Luke's Hospital, South Bethlehem, Pa., \$1,000; Allentown, Pa. Hospital, \$4,000, by the will of Mr. Araminta A. Hernan.

Conference of Women Physicians.—An international conference of women physicians is to be held at 600 Lexington Avenue, New York City, between the dates of September 15 and October 24, at which every medical woman in America and Canada is invited to be present. About thirty women physicians from foreign countries have already accepted invitations to be present. Belgium, China, Denmark, England, France, Holland, Italy, Norway, Scotland, Sweden and Switzerland will be among the countries represented. The hostess for the conference is the Social Morality Committee, National Board of Young Women's Christian Association, and the general purpose is to confer as to the attitude of social education along the lines of health and sex problems, together with the responsibilities related to them in foreign countries, and to discuss possibilities dealing with individual national problems.

The Education of Wounded Soldiers.—In a report issued from the Office of the Surgeon-General of the Army, July 8, it is stated that the staff supervising the work of educational service for the benefit of wounded soldiers at forty army hospitals totals 2,385 persons, consisting of 252 officers, 509 noncommissioned officers, 241 enlisted men, 1,274 reconstruction aids, 78 male and 31 female civilian employees. The largest staff was at Fort Sheridan, Ill., the number engaged in the work being 181. Walter Reed General Hospital at Washington, D. C., had the second largest staff—138. Of 2,524 patients receiving surgeon's certificate of discharge, 2,408 were able to resume their old occupations, or were not in need of retraining. Enrollments in war aftercare increased from 18,829 in April to 20,641 in May. Those in war academic studies increased from 30,358 to 31,248. The grand total of students in all forms of education was 56,850.

Research Fund Appropriations.—Appropriations were made, June 26, from the Educational Research and Development Fund of the United States Interdepartmental Social Hygiene Board to the following institutions for the purpose of organizing or completing the organization within those institutions of departments of hygiene, the curriculums of which shall include "courses and conferences in informational hygiene,

and courses, conferences and training in the applications of hygiene, emphasizing with appropriate and due proportion and proper tact and persistency the serious importance of the venereal diseases, their causes, carriers and prevention, and emphasizing at the same time the other important facts and applications of general hygiene, individual hygiene, group hygiene and intergroup hygiene."

Los Angeles, Calif., State Normal School; Natchitoches, La., Normal School; Maryland Normal and Industrial School (colored); Maryland State Normal School; Michigan State Normal School; Woono, Minn., Normal School; University of New Mexico, Valley City, N. D., Normal School; Reed College, Portland, Oregon; Bellingham, Wash., Normal School; University of Utah; Alcorn, Miss., A. & M. College (colored); Woman's Medical College of Pennsylvania; Harvard University; University of Missouri; Colorado State Teachers College; New York State Teachers College; Cornell University; University of South Carolina; Northwestern University; University of Pennsylvania; Ohio, Wash., State Normal School; Milwaukee, Wis., Normal School; Indiana University, Bloomington, Ind.; University of North Carolina.

An appropriation from this fund was made to a committee of psychologists under Dr. J. R. Watson of Johns Hopkins for

"the purpose of investigating the informational and educative effect on the public of certain motion picture films used in various campaigns for the control, repression and elimination of venereal disease."

Appropriations have been made to the following institutions from the Scientific Research Fund of the board for the purpose of discovering more effective medical measures in the prevention and treatment of venereal diseases:

1. Leland Stanford Junior University Medical School:

"Investigation into more effective treatment in acute and chronic gonorrhea." Under the direction of Dr. R. L. Rigdon, Chief, G. U. Clinic, and Dr. A. S. Spaulding, Professor of Gynecology.

"The permeability of the meninges to antisyphilitic drugs—an attempt to increase their permeability." Under the direction of Dr. H. C. McIlhenny, Professor of Neurology, and Dr. Thomas Addis, Director of the Laboratory.

"Investigation into more effective methods of treating syphilis." Under the direction of Dr. H. Addison, Associate Professor of Medicine.

2. University of Michigan College of Medicine and Surgery:

"A research for an improved method of demonstrating the spirochaeta pallida in human tissues." Under the direction of Dr. A. S. Warden, Director of Pathological Laboratory.

3. Johns Hopkins Medical School:

"Development of new synthetic drugs for the treatment of gonorrhea." Under the direction of Dr. L. C. White, Experimental Chemist to Brady Urological Institute.

"Manufacture and investigation of a series of new organic compounds in the treatment of syphilis." Under the direction of Dr. D. M. Davis.

"Manufacture and investigation of a series of penetrating organic dyes in the treatment of chancroids." Under the direction of Dr. E. A. Swartz.

"Experimental study of various methods of early treatment of venereal infection with the object of developing simpler technique, more efficient and less expensive drugs." Under the direction of Dr. William Jack.

4. University of Wisconsin Medical School:

"An attempt to prepare mercurial and arsenical compounds which have a predilection for the central nervous system, in the hope of finding drugs more useful than any known in the treatment of syphilis of the central nervous system." Under the direction of Dr. A. S. Loevenhart, Director of Laboratory.

5. University of Nebraska College of Medicine:

"An investigation relative to the development of an internal urinary antiseptic."

"On investigation of the value of certain anilin dyes in the treatment of gonorrhea." Both under the direction of E. G. Davis, M.D., Director of Pathological Laboratory.

6. St. Louis University College of Medicine:

"Studies in infection by gonococci." Under the direction of R. A. Kinsella, M.D., Director of the Department of Experimental Medicine.

7. Woman's Medical College of Pennsylvania:

"A serological study of syphilis in pregnant women and newborn children with special reference to the efficacy of the accepted methods of syphilitic treatment." Under the direction of Bertha M. Meane, M.D., Director of Research Department.

8. Washington University School of Medicine:

"The laboratory (biological) investigation of the latent syphilitic as a 'carrier'." Under the direction of Martin F. Engman, M.D., Professor of Dermatology.

"A study of hereditary transmission of syphilis." Under the direction of P. C. Jeans, M.D., Instructor and Associate in Pediatrics, and Jean B. Cooke, M.D., Associate in Pediatrics.

9. Cornell University Medical College:

"Serological study of the gonococcus group." Under the direction of John C. Torrey, Ph.D., Professor of Hygiene.

10. Jefferson Medical College of Philadelphia:

"A series of studies for the recognition and diagnosis of spirochaeta pallida in venereal diseases, and the effect of various drugs

and materials as germicidal agents against *spirocheta pallida*." Under the direction of Ramble C. Rosenberger, M.D., Professor of Hygiene and Bacteriology.

11. Yale University Medical School:

"Effect of anilin dyes, particularly Gentian Violet, on the gonococcus with reference to the growth of the organism in media containing the dye, and with reference to the effect on organisms in tissue (therapeutic effect)." Under the direction of J. M. Hunt, M.D., and J. W. Churchman, M.D., Professors of Surgery.

"An intensive study of methods for the isolation and identification of the gonococcus with a view to the determination of the homogeneity or heterogeneity of strains and their etiological relationships." Under the direction of George H. Smith, M.D., Assistant Professor of Department of Pathology and Bacteriology.

"The demonstration of syphilitic nature of unusual lesions encountered at the post-mortem table." Under the direction of M. C. Wintertz, M.D., Professor of Pathology and Bacteriology.

12. Union University Medical Department, Albany:

"For studies on the nature of the Wassermann reaction." Under the direction of Thomas Ordway, M.D., Dean and Associate Professor of Medicine.

"An attempt to produce generalized infection in lower animals with *spirocheta pallida* or with gonococcus." Under the direction of George S. Graham, M.D., Professor of Pathology, and W. M. Baldwin, M.D., Professor of Anatomy.

13. University of Minnesota Medical School:

"A study of the permeability of bacterial membranes, particularly the organisms of venereal disease." Under the direction of W. P. Larson, M.D., Chief, Department of Bacteriology and Immunology, and J. F. McClelland, Ph.D., Associate Professor of Physiology.

"Investigation of the chemical and physical properties of the cerebrospinal fluid in the luetic and nonluetic." Under the direction of L. G. Rowntree, M.D., Chief, Department of Medicine, and Charles E. Nixon, M.D., Instructor in Nervous and Mental Diseases.

"Investigation of phenol alcohol derivatives in relation to their analysis and chemotherapy of the gonococcus and spirochete." Under the direction of A. B. Hirschfelder, M.D., Chief, Department of Pharmacology, and H. G. Irvine, M.D., Assistant Professor of Dermatology and Syphilis.

14. Harvard University Medical School:

"An investigation of the properties contributing to the toxicity of arylpharmine, neoraphenamine and analogous products." Under the direction of Reid Hunt, M.D., Professor of Pharmacology.

FOREIGN

Red Cross Appropriations.—The American Red Cross has appropriated \$65,000 to enable the American Women's Hospital Association to send a mobile hospital unit to Serbia for relief work in connection with typhus and other epidemics. Of this amount \$25,000 is in cash and the balance in supplies.

Society Organized for the Study of Diets.—The *Policlinico* announces that the Società per lo studio della Alimentazione has been recently organized at Florence to study and coordinate research on questions of food for man and animals and to serve as a link between different fields of research and activity in this line. It is proposed to publish a journal and to have courses of lectures delivered to popularize normal standards for nutrition.

Serbia's Greatest Needs.—The death rate from tuberculosis in Serbia during the German occupation amounted to 1,453 per hundred thousand of population. There was also an alarming increase in infant mortality, typhus and influenza. In order to remedy this condition Col. Homer Folks of the Red Cross, who has recently made an exhaustive survey of the Balkan States, recommends the following necessities for Serbia: money, trained medical workers, health officers, medicines, hospitals, clinics, dispensaries, trained nurses, or organized public health agencies, district health nurses, and efficient campaigns for combating the usual epidemics of typhus and influenza, and the always present diseases of tuberculosis and scarlet fever.

Tribute to Golgi. Having reached the age limit of 75, Camillo Golgi retires from the chair of general pathology and histology at the University of Pavia, but he still retains charge of the institute connected therewith where he has been uninterruptedly at work for almost fifty years. A scholarship has been founded in his honor by his friends and pupils, the scholarship to be given to the orphan of some physician killed during the war. At an imposing ceremony he was presented likewise with a gold medal and souvenir album signed by the citizens of Pavia, with other honors. This discovery of the stain which first revealed the finer structure of the nervous system was made during his service in a small hospital at Abbiategrasso, remote from the centers of learning. The Nobel prize in medicine in 1906 was divided between Golgi and Ramon Cajal. Golgi is a senator and is of course an honorary member of many neurological and other scientific societies at home and abroad.

Memorial Hospital in London.—At an organized meeting held at the House of the Royal Society of Medicine, July 17, and presided over by Lord Redding, chief Justice of England, plans were discussed for the American Memorial Hospital to be erected in London at a cost of about ten million dollars. The purpose of the hospital is outlined in the following resolution: "That in commemoration of the cooperation of the medical men of the United States and of Great Britain during the European War, and to strengthen the friendship between the two nations, the American Hospital for Great Britain be, and is hereby founded for medical and surgical treatment of all classes, irrespective of creed, or nationality and for the promotion of scientific study and research." The following have been elected members of the American Medical Committee of the hospital: Drs. Albert J. Ochsner and Franklin H. Martin, Chicago, William J. and Charles H. Mayo, Rochester, Minn., and Rudolph Matas, New Orleans. Ambassador Davis heads the government council of the hospital, and the members chosen for the medical committee of Great Britain include Sir William Osler, Sir Ariathnot Lane, Sir Humphrey Rolleston, and Sir John Bland Sutton.

LATIN AMERICA

Personal.—Dr. Ricardo Mesa Torres of Talta, Chile, has just returned to his country after spending several months in the United States obtaining information in regard to medical and public health matters.

Sanitation in Uruguay.—At the suggestion of the secretary of public works, the government has decided to appoint a commission composed of physicians and engineers in order to study and report on the plans for sanitary works in various towns located in the interior of the country.

MEXICO LETTER

Mexico, July 21, 1919.

Yellow Fever Quarantine Still in Force

No new cases of yellow fever have been reported either in Yucatan or in the neighboring states. The port of Progreso has been dropped from the schedule of some of the steamboat companies to avoid the troubles caused by the existing quarantine. Although the Yucatan authorities are urging the raising of the quarantine on account of the losses suffered by the state, the department of public health has not granted as yet this demand.

Repeal of the Prohibition Penalty

The governor of Sonora has repealed the decree he had issued providing the death penalty for those dealing in alcohol.

Trade in Opium

A well organized corporation, the object of which was to smuggle into the United States large quantities of opium, has been discovered. It seems that this smuggling has been going on very smoothly for several years and that the opium received from China and stored in Mexico since before the war was reshipped to the United States in the form of a fluid extract called by the dealers "cooked opium," which was put in cans and sent through the custom houses as castor oil.

Malaria in the Army

It is reported that malaria is prevailing to an alarming extent among the troops on field duty in the zone north of Vera Cruz, in the neighborhood of the port of Tampico. The war department will take necessary measures to control the disease or at least to diminish its prevalence.

A Gift from Viscount Cowdray

Mr. David Muirhead, president of the British Society of Mexico, has received from Viscount Cowdray, the former Sir Wetman D. Pearson, a cablegram from London stating that Lord Cowdray and his wife have decided to give 1,000,000 pesos (about \$500,000) for the construction, equipment and maintenance of the new "Hospital Cowdray" to be founded in Mexico. Viscount Cowdray is one of the oldest oil men of Mexico.

Prize for the Discovery of Typhus Germ

The newspaper *El Universal* has just offered a prize for the discovery of the germ that causes tabardillo (typhus fever). The person who in the opinion of the National Academy of Medicine achieves this will receive \$25,000, the amount offered by Felix Palavicini, the manager of *El Uni-*

versal. Mr. Puccini has long been a promoter of noble endeavors. When secretary of public education he sent all medical quacks before the courts of justice. As a journalist he was a warm friend of the Allies. At present he is an earnest advocate of closer relations between Mexico and the United States and every week is devoting a certain space in his journal to scientific medicine. The conditions governing the contest relative to the discovery of the typhus germ will be approved by the Academy of Medicine before they are published.

Personal

Dr. Ernesto Cervera has been admitted as a member of the section of bacteriology of the Academy of Medicine after the thesis on hemolytic streptococci presented by him was approved by the section. Dr. Cervera is a professor in the school of medicine. He completed his studies in the Pasteur Institute of Paris.

Deaths

Edward Cowles ★ Plymouth, Mass.; Dartmouth Medical School, Hanover, Mass., 1863; College of Physicians and Surgeons in the City of New York, 1863; aged 82; captain and assistant surgeon, U. S. Army, from 1863 to 1872; resident physician and superintendent, Boston City Hospital, from 1870 to 1879; medical superintendent, McLean Hospital, Waverly, Mass., from 1879 to 1893; professor of mental diseases in Dartmouth Medical School from 1885 to 1914 and thereafter emeritus professor; instructor in mental diseases in Harvard Medical School from 1889 to 1914; trustee from 1890 to 1908 and nonresident lecturer on mental diseases at Clark University, Worcester, Mass., since 1904; one of the best known alienists of New England; author of many monographs on hospital construction, training of nurses and mental diseases; died at his home, July 25.

Malcolm McKinnon, Sandpoint, Idaho; Trinity Medical College, Toronto, Ont., 1895; aged 52; president of the Bonner County Medical Society in 1917; formerly surgeon to the Fosston (Minn.) Hospital; commissioned captain, M. C., U. S. Army, Nov. 8, 1918, and on duty at Camp Funston, Kan., and honorably discharged, Dec. 5, 1918; was instantly killed in an automobile accident near Baker City, Ore., recently.

Julius Francis Henkel, Detroit; Detroit College of Medicine and Surgery, 1896; aged 46; appointed lieutenant-colonel and chief surgeon of the Michigan National Guard, 1905; who had been in the military service since 1891, and in 1907 was elected president of the Detroit Light Infantry; a member of the Association of Military Surgeons of the United States; died at his home, July 22.

Isaac H. Cadwallader ★ St. Louis; Rush Medical College, 1875; aged 68; lecturer on materia medica and therapeutics in the Woman's Medical College for three years; a member of the staff of the Missouri Baptist Sanitarium since 1891, and physician in charge since 1900; died suddenly at his summer home at Arthur's Point, Minn., July 22, from cerebral hemorrhage.

Daniel Arnold Babcock, Fall River, Mass.; New York Homeopathic Medical College, New York City, 1874; aged 66; a member of the staff and secretary of the advisory board of the Union Hospital, Fall River; died in Boston, May 25, from cerebral hemorrhage.

George R. Pogue, Greeley, Colo.; Detroit College of Medicine and Surgery, 1892; aged 58; formerly of Grand Rapids, Mich.; a member of the Colorado State Medical Society; died at the Woodcroft Hospital, Pueblo, Colo., July 8.

Frederick William Koehler, Buffalo; University of Buffalo, N. Y., 1889; aged 52; a member of the Medical Society of the State of New York; medical inspector of the Buffalo Department of Health; died at his home, about July 18.

Andy Jackson Stewart ★ Provo, Utah; College of Physicians and Surgeons, Baltimore, 1904; aged 46; a specialist on diseases of the eye, ear, nose and throat; died at his home, May 25, from pneumonia.

Daniel Malloy Prince, Laurinburg, N. C.; Medical College of the State of North Carolina, Charleston, 1871; aged 71; a member of the Medical Society of the State of North Carolina; died at his home, July 16.

Melanchibon Marion Ritchie, Harrisburg, Pa.; Jefferson Medical College, 1874; aged 69; a member of the Medical

Society of the State of Pennsylvania; a veteran of the Civil War; died at his home, July 20.

Charles Conrad Abbott, Bristol, Pa.; University of Pennsylvania, Philadelphia, 1865; aged 70; a well known authority on animal and plant life in the United States; died at his home, July 29, from nephritis.

Louis Gally Wogan, New Orleans; Tulane University, New Orleans, 1903; aged 40; a member of the Louisiana State Medical Association; died in New Orleans, June 7, from pulmonary tuberculosis.

Thomas J. Brown, Winston-Salem, N. C.; Leonard Medical School, Raleigh, 1914; aged 32; a colored practitioner; also a pharmacist; died at his home, July 1, from septicemia, due to an infected wound.

William Albert Ross, Barrie, Ont.; Victoria University, Coburg, Ont., 1882; L.R.C.S. (Edin.) 1884; L.R.C.P. and S. (Lond.), 1885; aged 57; died at his home, May 15, from pernicious anemia.

William H. Becher, North Industry, Ohio (licensed, Ohio, 1896); aged 70; a member of the Ohio State Medical Association; a practitioner for fifty years; died at his home, July 16.

George W. Westbrook ★ Ma, Ga.; Atlanta (Ga.) Medical College, 1889; aged 53; president of the Ma Bank; died at his home, July 19, from cerebral hemorrhage.

Fred Bayard Lyon ★ Wichita, Kan.; Northwestern University Medical School, Chicago, 1903; aged 39; died at his home, July 20, from heart disease.

Josef Israel Manson ★ San Francisco; University of Syracuse, N. Y., 1897; aged 49; died at Brockway, Lake Tahoe, Calif., July 28.

John Louis Irwin, Chicago; McGill University, Montreal, 1879; aged 59; died at his home in Maywood, Ill., July 31, from heart disease.

Thomas Howell White, Yonkers, N. Y.; Yale University Medical School, New Haven, Conn., 1862; aged 80; died at his home, July 21.

Alphonse Lanoue, Ghent, Minn.; Laval University, Montreal, 1902; aged 49; died at the home of his niece in Holyoke, Mass., July 15.

Sumner G. Berry, Ashley, Ill.; Kentucky School of Medicine, Louisville, 1888; aged 52; died at his home, May 27, from accident.

William S. Clarke, Litchfield, Ky.; University of Louisville, Ky., 1886; aged 67; died at his home, May 20, from nephritis.

Frank H. Good, Reading, Pa.; University of Pennsylvania, Philadelphia, 1878; aged 64; died in the Reading Hospital, July 26.

Frederick William Weber, Baltimore; Baltimore University School of Medicine, 1888; aged 69; died at his home, July 22.

John W. Hobart, Richmond, Va.; Boston University, 1875; aged 80; died at his home, May 3, from cerebral hemorrhage.

David Cary, Fort Wayne, Ind.; aged 79; a practitioner for forty-two years; died at his home, July 9, from senile debility.

Walter B. Cowan ★ Dialville, Texas; Barnes Medical College, St. Louis, 1897; aged 47; died at his home, July 23.

John Wesley Monjar, Seneca, Pa.; Baltimore Medical College, 1899; aged 53; died at his home, July 9.

Marriages

RALPH DE BALLARD CLARKE, Lieut., M. C., U. S. N. R. F., West Haven, Conn., to Miss Lucy Emeline French of Winter Hill, Mass., June 28.

FRANK OSCAR BRUNCKHORST, Capt., M. C., U. S. Army, Hortonville, Wis., to Miss Amelia M. Rohrlack of Wyocena, Wis., June 12.

HENRY FRANKLIN SCHANTZ, Reading, Pa., to Miss Irene G. Clark of Niagara Falls, N. Y., at Reading, July 23.

JOHN THOMAS PERRY, Greenwood, Ark., to Miss Edith Louise McCullough of Fayetteville, Ark., July 17.

HENRY W. EDWARDS to Miss Audrey Simpson, both of Los Angeles, at Pico Heights, Los Angeles, July 14.

CHARLES E. GOODMAN, Virginia, Minn., to Miss Esther Gomberg of Duluth, Minn., at Detroit, July 18.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

RESTORIA

"Restoria for Bad Blood" is sold by the Restoria Chemical Company of Kansas City, Mo. The label declares the presence of "alcohol, 34 per cent."—an admission that is required by the Food and Drugs Act. Restoria is sold as a sure cure for syphilis. It is "The Miracle Medicine," "the Medicine of Last Resort," it is "Safer—Surer—Cheaper than the Serum Treatments," it contains "no mercury—no arsenic, ask the druggist." No information, of course, is given as to what Restoria contains, except the information that the law demands. It is said to be "of French origin, and has been

Restoria was first brought to the attention of THE JOURNAL in November, 1917, by a letter from the Council of National Defense, written by the chairman of the Subcommittee for Civil Cooperation in Combating Venereal Diseases. The letter stated that the Restoria concern had had the effrontery to write to the Venereal Disease Committee of the Council of National Defense, asking for a recommendation of Restoria! More than a year later—in April, 1919—a physician informed THE JOURNAL that there was an effort to finance Restoria, and samples had been sent to him at the request of a friend who had been invited to take some of the stock.

An unopened, original bottle of Restoria was submitted to the A. M. A. Chemical Laboratory, and tests were made to determine the presence or absence of mercury, arsenic or iodids. The chemist's report may be summarized thus:

Restoria contains no mercury or arsenic, but does contain iodid, probably potassium iodid, and calculated to potassium iodid corresponding to 1.693 grams in 100 c.c. It also contains much vegetable extractive, some alkaloidal drug, and a bitter oil or oleo resin.

RECOMMENDED BY UNCLE SAM FOR MALARIA

Quinine, One of the Three Ingredients of the Famous Malaria Medicine, Dr. Williams' No. 101 Tonic.

The United States Public Health Service at Washington recommends quinine for malaria, to which every reputable physician agrees. This is one of the ingredients of the popular malaria medicine, Dr. Williams' No. 101 Tonic, which is prescribed by quite a number of prominent physicians throughout the malaria belt. They say they get better results from it with their patients than if they prescribed straight quinine. Dr. Williams' No. 101 Tonic not only contains quinine, which kills the malaria germ, but also iron, which is a splendid tonic and increases the appetite. The third ingredient is magnesium, which regulates the bowels. Dr. Williams' No. 101 Tonic is therefore a well-balanced efficient remedy. Try a bottle. Your druggist can supply you.—ADV.

PUBLIC HEALTH REPORTS

VOL. 31

MARCH 21, 1919

No. 12

MALARIA.

A SERIOUS HEALTH PROBLEM OF NATION-WIDE CONCERN.

The public generally has no conception of the seriousness of the malaria problem in the United States.

which has been bred. The more general use of quinine as a household remedy together with a commendable diminution of faith in widely advertised patent medicines, is probably also responsible for some of the improvement observed.

On the left is a reduced reproduction of a "patent medicine" advertisement which carelessly read—and probably most "patent medicine" advertisements are carelessly read—may give the impression that the United States government has recommended the use of quinine in the treatment of malaria, was supplemented by the statement that the "diminution of faith in widely advertised patent medicines" was doubtless responsible for the fewer cases of malaria today. The advertiser of "Dr. Williams' No. 101 Tonic" apparently overlooked the latter statement.

known and prescribed throughout Continental Europe for more than fifty years."

While Restoria is recommended for rheumatism, kidney trouble, lumbago, eczema, and the omnipresent "catarrh," it is especially and particularly featured for syphilis or "blood poison." Here are some of the things the booklet has to say regarding syphilis and its treatment with Restoria and by other means:

"Phosphorus goes to the seat of the disease. It cleanses the Blood, as it were, eradicating from it every trace of the Syphilitic virus."

"One month of Phosphorus treatment may be equal to the services of the most competent specialists, for whose skill you would be required to pay hundreds of dollars."

"The average doctor finds this dreadful malady [syphilis] as only a nuisance, and the patient is looked upon as a horrible example, on whom a little of his time, practice and profit while he prescribes." "The average physician is utterly incapable of handling this dread (dreadful) disease. He lacks the experience, but he will not tell you so. He will tell you that he does not possess. He will do the best he can for you. He will tell you with mercury or arsenic, perhaps, and make a useless work of you in time; and all the while charge you \$10.00 to \$20.00."

"The unfortunate Syphilitic is considered common prey, and any physician is satisfied in trying anything on him, and charging three times the value."

Correspondence

DRAINAGE AFTER CHOLECYSTECTOMY

To the Editor.—A very recent personal experience with a cholecystectomy and cholecystotomy followed by T tube drainage of the common duct leads me to make some comments on the experience for the benefit of those practicing this procedure.

The most annoying symptoms following the operation, aside from the pain produced by coughing, sneezing and the like, were those referred to the stomach. These symptoms were similar to those experienced at intervals for years prior to the operation, and consisted of an almost continuous nausea accompanied by a terrific burning in the epigastrium. After a time vomiting would occur followed by a period of relief of the burning and nausea; but the act itself, which was resisted as long as possible, was accompanied by excruciating pain in the wound, and the muscular effort involved was sufficient to break one of the silk-worm-gut stitches.

It was found that a quarter grain of morphin would give relief from these symptoms long enough to allow of several

hours' rest and the ability to take some food once in the twenty-four hours, so that for two weeks, the length of time the tube was allowed to remain, my daily diet consisted of a piece of toast and coffee. This resulted in the loss of 20 pounds in weight in the two weeks.

The withdrawal of the drainage from the bed of the gall-bladder and the tube from the common duct was followed by the immediate relief of these symptoms and rendered the morphin unnecessary. The bowel end of the T tube was found occluded by a stone on its withdrawal, which accounted for the clay-colored stools and the large biliary drainage from the wound. This fact demonstrates the etiologic relationship between the stomach symptoms and the presence of foreign bodies in the gallbladder or common duct or the absence of bile from the intestine, or both.

I have been led to wonder why a tube is ever placed in the common duct. As George Crile said in a discussion of this subject before the Chicago Surgical Society, "Why drain a drain?" If the common duct is patent, the tube is not needed because it makes little difference whether pus or toxic material is drained into the bowel or outside the abdomen. It does no harm in the bowel. If the common duct is not patent, it must be made so before the operation is completed and the tube again is not needed. Then, too, the presence of the tube in the duct is not unproductive of harm. If it fits too tight it may cause necrosis of its walls. It is an invitation to the deposition of cholesterol and bile salts; and, lastly, it is the cause of distressing nausea, and vomiting and pyrosis, which militate against the patient's recovery.

It is in the hope that others who are obliged to undergo this operation may have a more satisfactory convalescence that this personal experience is related.

BUDD VAN SWERINGEN, M.D., Fort Wayne, Ind.

THE PRODUCTION OF SHOCK

To the Editor:—In THE JOURNAL, July 19, 1919, p. 178, Cannon makes the statement in a footnote that "Meltzer (*Penn. M. J.* 22:129 [Dec.] 1918) has stated that I became 'converted to the theory that the most essential factor in the production of shock is acidosis.' I have never published the idea that there was in the acidosis of shock a primary cause for the low pressure." This is literally true. Cannon has nowhere stated in clear words that he is of the opinion that, in shock, acidosis is the primary cause for the low pressure. But one comes to such a conclusion from various statements which Cannon made in his article on "Acidosis in Cases of Shock, Hemorrhage and Gas Infection" (THE JOURNAL, Feb. 23, 1918, p. 531). On page 532 there is the statement: "From the evidence presented above, the conclusion is warranted . . . that as a general rule the lower the pressure the lower the [alkali] reserve. . . . Cases of blood pressure due to shock . . . have a diminished supply of alkali in the blood. As a general rule, the lower the pressure, the more marked the acidosis. . . . Shocked men . . . can be quickly relieved of their distress by intravenous injection of a solution of sodium bicarbonate." Page 615: "There is evidence that acid or change in the blood in the direction of acidity may have depressive effects on the blood pressure." Page 616: "As acid develops in tissues poorly supplied with oxygen, the blood vessels locally affected by these acids may reasonably be expected . . . to undergo relaxation." I was especially impressed by a statement of Bayliss (*J. Physiol.*, 52, Proc. Physiol. Soc., xviii): "These recent experiments have led me to modify the point of view which experiments previously done in conjunction with Captain Cannon had inclined me to take. They compel me to look on acidosis and its treatment as of secondary importance." This statement implies that Bayliss entertained previously the view that acidosis is the primary cause of the low blood pressure in shock, a view which was formed on the basis of experiments which he carried out together with Cannon. It did not occur to me that two such authors as Bayliss and Cannon, working together, would entertain at the time of their work a different notion as to the primary cause of acidosis and both should nevertheless recommend the intra-

venous injection of sodium bicarbonate for the treatment of shock. My term that Cannon became converted was used because I believe that Wright was the first one to recommend the use of sodium bicarbonate.

I did not discuss the correctness of certain theories of shock. It was, as I stated, "an appeal to physiologists . . . to adhere firmly to the careful, critical methods which they are in the habit of employing in their physiologic researches, even if by doing so, as a consequence, the actual yield to medicine may be slow and, perhaps, even small." That appeal was, and still is, well founded.

S. J. MELTZER, M.D., New York.

[NOTE.—The letter of Dr. Meltzer was referred to Dr. Cannon, who replies:]

To the Editor:—From an investigator's statement of facts to draw a conclusion which he did not, then to attribute to him that conclusion, and finally to criticize him for drawing the conclusion seems to me not a good example of adhering to "careful, critical methods." I quite agree that Dr. Meltzer's appeal was, and still is, well founded.

W. B. CANNON, M.D., Boston.

TEETH FORMATION IN EPILEPSY

To the Editor:—I would like to ask through THE JOURNAL, if any physicians have observed a condition which I have found in the mouths of epileptics and also those mentally weak? Having had the privilege, for several years, of seeing the roentgenograms of the teeth of these individuals, I have found that in most cases the apexes of the teeth, if fully formed, were blunted to a marked degree, and in some there was only partial root development.

I make this inquiry, thinking that it may lead to further investigation by others better equipped.

GEORGE B. MCCLINTOCK, D.D.S., Cincinnati.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TONSILS AS FOCI OF INFECTION

To the Editor:—Kindly advise me where I can get literature on diseased tonsils and their relation to other constitutional conditions.

AUSTIN M. GROVE, York, Pa.

ANSWER.—The following references may be consulted:

SKIN INK FOR OPERATIVE WORK

To the Editor:—Please publish a formula for a skin ink to be used in operative work, which will not be removed by water, alcohol, ether or benzoin.

L. N. New York.

ANSWER.—N. S. Finzi (*Brit. M. J.* 1:52 [Jan. 12] 1918; *abst. The JOURNAL*, Feb. 23, 1918, p. 573) uses a 5 per cent. pyrogallol and 2 per cent. iron solution, made as follows: pyrogallol acid, 1 gm.; denatured alcohol, 10 c.c.; solution of ferric chlorid, 2 c.c., and acetone, sufficient to make 20 c.c. This solution is kept in a bottle with a camel's hair brush attached to the cork. The mark on the skin is brownish gray at first, but after a few hours it turns a brilliant black.

Georgia March Examination

Dr. C. T. Nolan, secretary of the Georgia State Board of Medical Examiners, reports the written examination held at Atlanta, March 4-5, 1919. The examination covered 10 subjects and included 100 questions. An average of 80 per cent. was required to pass. Twenty-six candidates were examined, all of whom passed. Thirteen candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Emory University (1919)	85.4, 86.2, 86.8, 87.4, 87.5, 87.9, 88.1, 88.2, 88.3, 88.5, 89.2, 89.5, 89.5, 89.8, 90.3, 90.8, 91.1, 91.5, 91.6, 91.8, 92.1, 92.7.	(1918)	95.4

Indiana February Examination

Dr. William T. Gott, secretary of the Indiana State Board of Medical Registration and Examination, reports the written examination held at Indianapolis, Feb. 26-28, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Thirty-seven candidates, including three osteopaths, were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Indiana University (1919)	85.3, 86.7, 87.4, 87.7, 88.3, 88.5, 88.6, 88.7, 89.2, 89.3, 89.6, 89.6, 89.7, 89.9, 90, 90.1, 90.1, 90.6, 90.6, 90.9, 91, 91.4, 91.7, 91.7, 92, 92.1, 92.3.	(1916)	86.9, 91.8
Johns Hopkins University		(1918)	87.1
Harvard University		(1918)	87.1
Dartmouth Medical School		(1904)	87.5
McLarey Medical College		(1914)	80.3
National University, Athens		(1884)	77.1

Dr. Gott also reports that 26 candidates, including 2 osteopaths, were licensed through reciprocity, from Aug. 1, 1918, to April 17, 1919. The following colleges were represented:

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Chicago College of Medicine and Surgery	(1913), (1914)	(1915)	Illinois
Illinois Medical College	(1908)	(1908)	Illinois

Iowa March Examination

Mr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Iowa City, March 24-26, 1919. The examination covered 8 subjects and included 100 questions. An average of 75 per cent. was required to pass. Fifty candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery.....	(1917)	90.1, 93.5	
Rush Medical College	(1917)	90.1, 93.8	
University of Illinois.....	(1919)	94, 90.5	
State University of Iowa College of Medicine (1919)	81.8, 85.2, 85.2, 86.7, 87.1, 87.3, 87.5, 87.6, 88.1, 88.2, 89, 89.1, 89.3, 89.5, 89.5, 89.8, 90.1, 90.1, 90.2, 90.5, 90.5, 90.7, 90.7, 90.8, 91.1, 91.3, 91.3, 91.5, 91.6, 91.6, 91.8, 91.8, 91.8, 92.1, 92.5, 92.6, 92.6, 93.2, 93.7, 93.8, 93.8, 94.8.		
University and Bellevue Hospital Medical College.....	(1903)	83.5	
University of Pennsylvania.....	(1917)	88.6	

The following candidates were licensed through reciprocity, April 29, 1919:

College	Year Grad.	Reciprocity with
American College of Medicine and Surgery	(1905)	Illinois
Chicago College of Medicine and Surgery	(1919)	Illinois
Illinois Medical College	(1908)	Illinois

St. Louis Medical College	(1880)	Missouri
St. Louis University School of Medicine (1917)	Missouri; (1915) Missouri	Missouri
Univ. Med. Coll. of Kansas City (1892)	Nebraska; (1910)	Kansas
John A. Creighton Med. College	(1901), (1916), (1919)	Nebraska
University of Nebraska	(1910)	Nebraska
Eclectic Medical College, Cincinnati	(1916)	Nebraska
Ohio Medical University	(1902)	N. Dakota

Oklahoma April Examination

Dr. J. J. Williams, secretary of the Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City, April 8-9, 1919. The examination covered 11 subjects and included 110 questions. An average of 60 per cent. was required to pass. Five candidates, including 1 osteopath, were examined and passed. Twenty-six candidates, including 3 osteopaths, were licensed through reciprocity, and 12 candidates were granted re-registration licenses. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Bennett Medical College	(1919)	78
Chicago College of Medicine and Surgery	(1917)	70

Book Notices

TRAITEMENT DES PSYCHONEVROSES DE GUERRE. Par G. Roussy, Agrégé à la Faculté de Paris, J. Boisseau, Ancien Interne des Hôpitaux, et M. d'Elmsitz, Ancien Interne des Hôpitaux. Papier, Price, 4 francs. Pp. 191, with illustrations. Paris: Masson et Co, 1918.

This small volume is really a sequence to "Psychonevroses de Guerre" by Roussy and Lhermitte, in which the general principles of treatment were considered. In the meantime, Roussy, Boisseau and D'Elmsitz, having had exceptional opportunities for the study and treatment of war neuroses, have accumulated a number of conceptions and convictions concerning these disorders. Their ideas are embraced in the present work. The authors very pertinently remark that the analytic study of therapeutic results, especially of the mode of disappearance of a nervous disorder, naturally helps one to understand the mechanism of inception and the evolution of such disorder.

As most French authors are fairly well agreed as to the ordinary types of neuroses, their nature and treatment, the authors of the present volume have devoted especial study to the type of trouble specially emphasized by Babinski and Froment, called by them "physiopathic" or of "reflex nature." Babinski and Froment maintain that these cases are not purely functional and that they cannot be shown to be organic in the ordinary acceptance of the term. With the conclusions of Babinski and Froment the authors of this work take positive issue. They believe that such cases are essentially psychopathic or psychogenic, and that such circulatory and trophic abnormalities as may be present are purely secondary. For instance, in an old case of hysterical paralysis with contracture, there is the paralysis and contracture which can be rapidly removed by appropriate psychotherapy and which disappeared during general anesthesia. But there have been in the course of time added to the functional disorder changes in the joint similar to those found after fracture when the extremity has been too long immobilized. These changes, of course, do not disappear under general anesthesia and are only gradually removed by physiotherapy.

In Chapter I there are brief descriptions of the multitudinous types of disability, types which sometimes depend on the particular anatomy and physiology of the joint involved. Chapter II is devoted to the steps of birth and fixation of a neurosis, without any profound psychologic analysis, and Chapter III to practical prophylaxis in the army.

With Chapter IV we reach the details of treatment. The authors divide their procedure into: (1) preparation; (2) relief from the motor trouble ("unhooking," detachment, uncoupling); (3) fixation (of the result obtained), and (4) training, medical and military. Of these they think the first perhaps the most important. The object is to procure the proper mental attitude. This is begun by an intelligent and detailed examination. Then the patient is informed that he is curable and is going to be cured. Next he is placed in bed under proper influences. These embrace encouraging, explanatory and sympathetic but authoritative talks by a competent physician; talks with and letters from comrades who have been cured; stories by the nurses of brilliant successes; the placing of a patient with an inveterate case in a ward of men convalescent from similar trouble, etc. Not until the patient has reached "psychic maturity" is the next step taken. And the authors insist that the physician must also be ready—in good form; for the next move involves a mental contest between patient and physician from which the latter must emerge victor. Occasionally, if the preparation has been imperfect, the struggle may last two or three or four hours; but the physician is not to desist until his result is attained. Details of the physician's armamentarium and technic must be read in the original. Steps 3 and 4 follow the general lines recognized by all neurologists. This chapter is illuminated by a citation of striking cases and by convincing photographs. It seems incredible that paralysis and contracture of the hand with "hoxing glove" edema, all of thirty-three months' duration, could disappear in eighteen hours. But such is one illustrative case.

Chapter V contains detailed consideration of the various conditions grouped by Babinski under the term "physiopathic." The authors are not able to clarify all of them; but for the vast majority their explanations seem to be quite adequate. This chapter gives the results of very important investigations. A short chapter on prognosis and an excellent bibliography terminate the volume. No neurologist can afford to be without it, and every one attempting to treat functional nervous disorders should read it. We believe there is now an English translation.

THE SOLDIER'S HEART AND THE EFFORT SYNDROME. By THOMAS LEWIS, M.D., F.R.C.P., F.R.S., Physician of the Staff of the Medical Research Committee. Cloth. Price, \$2.25 net. Pp. 144. New York: Paul R. Hoeber, 1919.

The views of Thomas Lewis concerning the "effort syndrome" are well known, especially through the report of the Medical Research Committee and the frequent references to it and quotations from it in current medical literature. It is well, however, to have these views, matured by added experience and authoritatively revised, in convenient and compact form, as in this attractive little volume. The "effort syndrome" is here fully considered as to nature, symptoms, prognosis and treatment. There are also discussed other cardiac disorders of soldiers. One notes with hearty approval the emphatic protest against assigning too much importance to the cardiac murmur. At the same time we feel that there is a real danger that Lewis, as well as Mackenzie, has made such extreme statements about the insignificant value of the systolic murmur from the standpoint of both diagnosis and prognosis that through his powerful influence the profession at large will come to believe that all endocardial murmurs are practically negligible. Such a belief, if the basis of practice, would be decidedly harmful. While much that is contained in the book is of purely military application, there is a great deal that will bear transfer to civil practice. The volume will be found useful, therefore, not only in the army but also by the physician in private or hospital practice. The style is the orderly, lucid style that we have come to associate with the name of Thomas Lewis, though it does not, as it seems to us, come up to the standard of his other writings. Perhaps more deliberate revision, with pruning, will remove some evidences of haste. Certainly some of the loosely constructed sentences of the preface ought not to be allowed to stand in their present form.

WAR, SCIENCE AND CIVILIZATION. By William Emerson Ritter, Director of the Scripps Institution for Biological Research of the University of California. Cloth. Price, \$1.25 net. Pp. 125. Boston: Richard G. Badger, 1919.

This book, written in 1915, reflects the views of a certain number of college and university teachers in the early years of the war. Two statements on the first page would probably not be made today, even by a biologic student of warfare. "It is incumbent on the people of our country to give more heed to one of Germany's claims than so far we have given. We must grant that she deserves 'more room in the sunshine' than she has." The verdict of the civilized world today is that Germany has forfeited any claims she might have had to a "room in the sunshine" and that she deserves principally a protracted period of repentance and restitution. The other statement is: "We gladly recognize that the good Germany has done mankind generally by cultivating the sciences and arts of peace outweighs the harm she has done in promoting war." Few will agree with Professor Ritter in this statement. Even if the author believed it at the time he wrote it, Germany has a long debit account on her balance sheet, and it has grown beyond belief in the last four years. Another view advanced by the author is the voluntary surrender of Hawaii to Japan on the ground that Japan needs land and that we have more than we need. By the same reasoning, we should have given away everything west of Pittsburgh after the Revolutionary War. The aim of the writer is to illuminate civilization and international relations by the pure white light of biologic science. The first problem, he says, is to find the way "whereby the nations of the world, some of which truly need a larger share of Nature's wealth than they possess, while others possess more

than they really need, may adjust their relative needs without resorting to war." He asks, "Is an international arrangement possible whereby a nation might under certain circumstances give over to other nations portions of its territory or other economic advantages peacefully, deliberately, and without immediate and definite compensation?" His own answer is "No, as long as politics, national and international, rest on a philosophy of nature and human nature as defective as that upon which they now do rest; but yes, if political practice could be based on a philosophy that should conform to the actual facts of nature and human nature." Most readers will, we think, disagree fundamentally with this statement. Political practice is today based on the actual facts of nature and human nature rather than on idealistic and abnormal unselfishness. Nations as well as individuals are subject to the struggle for existence and survival of the fittest, and must feed their own children before they give to others. Professor Ritter's views were hardly timely in 1915, and they are still less so at present.

PERSONAL IDENTIFICATION: METHODS FOR THE IDENTIFICATION OF INDIVIDUALS, LIVING OR DEAD. By HARRIS HAWTHORNE WIDDER, Ph.D., Professor of Zoology in South College and Port Wentworth, South Carolina. Price, 85 cts. Pp. 374, with illustrations. Boston: Richard G. Badger, 1918.

Since human beings are not registered regularly by the government—in many places not even at the time of their birth—it is not infrequent for a human being to become lost from his community and, through lack of any means of identification, to disappear as if—in the words of the "Hum"—he had been "sunk without a trace." For many years the chief interest attached to personal identification lay in its relationship to the proving of guilt of those who had violated the law. It has frequently been necessary, however—and is daily becoming more so—to prove identification in connection with such legal problems as inheritance, when death occurs by burning, drowning, or other mutilating causes. In this book the authors consider identification as it is made by all of the various methods thus far known. The work is divided into two parts, describing, first, methods which furnish partial identification, including the more common marks, such as general configuration, moles, scars, habits and voice, and, second, methods which furnish absolute identification, including finger prints, palm prints and foot prints. The book is illustrated throughout by interesting cases and instructive pictures, including legal controversies in which personal identification figured prominently. To all physicians interested in medicolegal subjects this book will appeal particularly.

MILITARY SURVEY OF THE EAR, NOSE AND THROAT. By HARRY W. LACK, M.D., Major, Medical Reserve Corps, U. S. A. Medical War Manual No. 8. Authorized by the Secretary of War and under the Supervision of the Surgeon-General and the Command of National Defense. Edition. Price, \$1.25. Pp. 176. Philadelphia: Lea & Febiger, 1918.

In this booklet the author reviews the surgical literature of the present war on the subjects included in the title. The book was prepared primarily for the use of commissioned otolaryngologists; and, as these are presumed to have had elementary training, it makes no presentation of elementary principles. The author presents references to more than 500 bibliographic articles from recent British, German, Italian, French and American literature.

PRINCIPLES OF FERTILIZATION. By LEON KATZMAN, LL.D., Professor of Zoology, University of Chicago. Cloth. Price, \$1.75. Pp. 112. Chicago: The University of Chicago Press, 1918.

Since the two primary impulses of all life are self preservation and the preservation of the kind, man has always been interested in the method of reproducing his kind and in the various biological and pathological factors that are involved. The author relates the story of early studies on this subject, from the earliest attempts to describe the morphology of fertilization, through the discovery of the sperm cell and all the processes of fertilization, to the problem of specificity in fertilization and the problem of inheritance. The theory of Dr. Laib has been

that the spermatozoon undergoes some activation necessary for its part in the internal events of fertilization; in other words, that the spermatozoon itself needs to be fertilized and that this takes place on its passage through the cortex of the ovum. In presenting other theories of activation, the author points out the plausibility of this particular view. To those already well grounded in elementary embryology, this book will form an enlightening second step.

Medicolegal

Valid Law—Meaning of Word "Medicine"—Neuropathy

(*Commonwealth v. Seibert* (Pa.), 105 Atl. R. 507)

The Supreme Court of Pennsylvania, in affirming a judgment that affirmed a conviction of the defendant, a neuropath, of practicing medicine without a certificate of licensure, holds constitutional the statute of that state which makes it unlawful for any person to engage in the practice of medicine and surgery, or to hold himself forth as a practitioner in medicine and surgery, or to assume the title of doctor of medicine and surgery, or doctor of any specific disease, or to diagnose diseases, or to treat diseases by the use of medicines and surgery, or to sign any death certificate, or to hold himself forth as able to do so, unless he has first fulfilled the requirements of this act and has received a certificate of licensure from the bureau of medical education and licensure and has had such license duly recorded.

The court says that the determination of the several inquiries raised must depend on the proper understanding to be derived from the words of the statute involved. Of controlling importance in this connection is the word "medicine," a word susceptible of distinct meanings; one indicating nothing more than a remedial agent that has the property of curing or mitigating diseases, or is used for that purpose, while the other indicates an art of healing or science which has for its province the treatment of diseases generally. The latter has much the wider and more comprehensive significance, of course, and while, as so used, it may be in a sense technical, yet unquestionably the wider is the popular sense in which it is employed and understood. Furthermore, whatever is technical in it has been so far popularized by common usage and understanding that no one, however unlearned, can fail to observe the true distinction between medicine as a drug and medicine as a science or profession. It is in the latter sense that the word is employed in the statute.

The one danger provided against was, not the promiscuous sale of drugs or other remedial agents, but the unrestricted and unregulated practice of medicine or the art of healing; medicine here being used to denote an art or science having for its object the cure of diseases and the preservation of health, whether with aid of drugs or any remedial agencies whatever. The manifest and only purpose of the statute was to confine the right to invite public confidence in the skill and efficiency of those who would hold themselves out to the public as medical doctors, to those only who have had an examination by an impartial board of examiners created by the statute and acting for the state, and have been accredited by the board as having met the requirements of the law and received its license.

Giving the act this interpretation, the defendant by his conduct brought himself unquestionably within its terms; he engaged in the practice of medicine, that is, he held himself out to the public as one instructed and skilled in the healing art. By printed sign exposed in front of the office, styling himself as Dr. J. A. Seibert, Neuropath, he represented himself as skilled in the healing art, and invited the confidence and patronage of the sick and afflicted generally. The distinction that was sought to be made between neuropathy and medicine could avail the defendant nothing if it be kept in mind that the legislative meaning of the latter word, when used in the expression "practice of medicine," covers and embraces everything that by common understanding is included in the term healing art. The defendant held himself out to the public and invited its confidence and patronage as

a "practitioner of neuropathy." The use of this term necessarily implied that he was skilled in the science of pathology, a science which unquestionably has for its province "the treatment of diseases, their nature, causes, progress, manifestations and results." This to the lay mind, no less than the professional, would import that neuropathy was a branch of medicine. What more could be said of allopathy, homoeopathy or any other science of healing with such termination as its adopted designation?

Quarantine and Habeas Corpus

(*Ex parte Hardcastle (Texas), 208 S. W. R. 531*)

The Court of Criminal Appeals of Texas, in ordering that a writ of habeas corpus be granted, says that the relator was held under an order of the city health officer of San Antonio, by virtue of quarantine regulations established in accord with Chapter 85 of the acts of the fourth called session of the thirty-fifth legislature, under a statement of the order of arrest that, according to the information of the health officer, the relator was affected with gonorrhea. It was agreed that the sole issue in the case was whether or not the decision of the proper health is final or whether it can be inquired into by writ of habeas corpus.

The legislature, under the police power, has authority to authorize the establishment of quarantine regulations for the protection of the public against contagion from those persons whose condition is such as to spread disease, and, incident thereto, to authorize the arrest and detention of such persons; and such, the court understands, is the purpose of the statute in question. Under its terms, the proper health officer may issue a warrant by virtue of which a lawful arrest may be made without preliminary thereto affording the person affected a hearing; but if, after arrest, such person challenges the right of the authorities to continue the detention, the fundamental law accords him the right to have the legality of his detention inquired into by a proper court in a habeas corpus proceeding. The law denies to no one restrained of his liberty without a hearing the right to prove in some tribunal that the facts justifying his restraint do not exist. The health authorities causing the arrest of the relator derived their power to do so from the alleged existence of the fact that the relator was affected with the disease mentioned, and that her detention was required in the public interest to prevent contagion. If those facts did not exist, the officer had no jurisdiction to continue the restraint, and the court in the habeas corpus proceeding has authority to inquire whether the facts essential to jurisdiction exist.

The decision of the Supreme Court of Washington (*State v. Superior Court for King County, 174 Pac. R. 973*), to which this court was referred as illustrating an exception to this rule, does not, this court thinks, extend so far as to support the contention that the decision of the health officer who ordered the arrest of the relator was conclusive against her right to an inquiry in a habeas corpus hearing touching the existence of the facts on which such officer acted. The Washington decision construed a statute passed under a special provision of the constitution of that state, authorizing the "establishment of boards of health with such powers as the legislature may direct." The statute enacted under this power did not make the initial order of arrest conclusive, but established the board of health as a forum of appeal, and specially provided that its decision reviewing that of the health officer should be final.

The Texas constitution, unlike that of the state of Washington, contains no special provision on the subject; but the power to establish quarantine, as existent under the Texas constitution, is an incident of the police power vested in the legislature under the general power to pass laws. The Texas statute does not declare that the initial order of arrest shall be conclusive; nor does it designate any tribunal to which one detained under an order of arrest issued by the health officer may appeal for a hearing. The fair and reasonable interpretation of the statute under which the relator was held is that which accords the health officer the power to order arrest and detention, leaving to the person detained the right to invoke the decision of the established judicial

tribunals of the state on questions raised, either of fact or of law, involving the validity of the detention. Wherefore the court concludes that, under the act of the legislature in question, the relator had the right to a hearing on writ of habeas corpus, and therein to prove the nonexistence of the facts necessary to authorize her continued detention and thereby obtain release.

State Board of Health Requiring Vaccination

(*Rhea v. Board of Education of Devils Lake Special School District (N. D.), 171 N. W. R. 103*)

The Supreme Court of North Dakota, in reversing a judgment that was rendered in favor of the defendant in this mandamus case growing out of the exclusion from the public schools maintained by the defendant of the plaintiff because he had not been vaccinated, says that, while the researches of counsel and the investigations of the court had failed to disclose the existence of any direct authority on the exact question presented under the facts in this case, it appears that there are ample precedents for the principles which the court deems controlling. Boards of health and boards of education possess only such powers as the statutes confer on them. The power to legislate cannot be delegated to them; but when the legislative policy is determined by the competent legislative authority, ample administrative powers may be vested in executives or boards to the end that the legislative rule may be properly enforced.

It was alleged that the defendant board of education, claiming to act under and pursuant to an order of the state board of health, made an unlawful order requiring that all pupils should be vaccinated before being admitted to the public schools of the district; and it was contended on behalf of the defendant that, since Section 425 of the Compiled Laws of North Dakota of 1913 requires the vaccination of minors generally, it was proper for the state board of health to promulgate an order which would not affect adversely any one who had complied with the statute. However, the failure to comply with the compulsory vaccination statute results in making the one who thus fails guilty of a misdemeanor, and subjects him to the prescribed punishment. It is not particularly the function of the board of health to compel compliance with this statute. The board is not the public prosecutor. Even the public prosecutor could not compel vaccination. He can only punish for violations of the statutes, and to exclude one from school on the same ground would be to add a penalty not included in the statute. The powers of the board of health are limited to such needful rules and regulations as may be required for the prevention and spread of contagious and infectious diseases, and the fact that the legislature has purported to make vaccination compulsory does not add to or subtract from the scientific data on which the board of health may determine whether or not a proposed rule or regulation is "needful." The authorities uniformly hold that a board of health, constituted as that of North Dakota is, possessing requisite general powers for the prevention and spread of contagious diseases, cannot promulgate and enforce rules which merely have a tendency in that direction, but which are not founded on any existing condition, or on a danger not reasonably to be apprehended.

Section 400 of the Compiled Laws of 1913, making it the duty of the board of health to make and enforce all needful rules and regulations for the prevention and cure of contagious and infectious diseases, is held not to authorize the board of health to issue an order denying to children the right to attend the public schools except on the condition of being vaccinated, when it appears that there is no prevailing epidemic of smallpox, or no imminent danger from this disease is reasonably to be anticipated.

Sections 1346 and 420 of the Compiled Laws of 1913, defining the duties of school officers with reference to the supervision of the health of schoolchildren and their exclusion from schools when infected with infectious or contagious diseases, the court construes and holds not to authorize the exclusion for nonvaccination, in the absence of a showing of danger due to the existence of smallpox in the community, or that such danger is reasonably imminent.

AMERICAN ASSOCIATION OF ANESTHETISTS

Seventh Annual meeting, held at Atlantic City, N. J., June 9-10, 1919

(Concluded from page 361)

SYMPOSIUM ON ANESTHESIA FOR WAR SURGERY

A Plea for Chloroform

DR. WILLIAM B. HOWELL, Montreal: Whether from climatic conditions or a difference in the quality of the ether supplied, or possibly owing to the special type of patient, many of whom were given to excessive cigaret smoking, ether alone was not as satisfactory an anesthetic as in civilian surgery, and many anesthetists were glad to turn to the free use of chloroform. The majority of soldiers coming to operation were wounded only slightly, and apart from their wounds, were in excellent physical condition. They were highly resistant to ether and inclined to shout and struggle during induction. While induction could be facilitated by the preliminary use of nitrous oxide-oxygen or ethyl chlorid, when available, their lack plainly indicated the efficiency of chloroform in getting large numbers of wounded rapidly ready for the surgeons. Chloroform, in war surgery, should be used only by those experienced in its administration, and then preferably by means of a dosimetric apparatus like that of Vernon Harcourt. Depth of anesthesia and significance of danger symptoms cannot be gaged accurately when chloroform is given on the open mask. A dosimetric inhaler enables the anesthetist to know what he is doing and to escape the dangers incident to fibrillation during induction from too light anesthesia. While atropin is not necessary before chloroform anesthesia, morphin may be used, if given in moderation. Oxygen and warmth give chloroform additional safety. When the respiratory system is embarrassed by incipient tuberculosis, emphysema, coryza, bronchitis or empyema, chloroform may be used with considerably more satisfaction than other anesthetics and with better results. Chronic bronchitis, or "Flanders cough," was very prevalent in the Ypres district and accounted to some extent for the popularity of chloroform. In strong, muscular soldiers, chloroform is especially adapted for the reduction of dislocations and the setting of fractures.

Effects of Ether and Nitrous Oxide-Oxygen Anesthesia in Cases of Shock and Hemorrhage

DR. W. B. CANNON, Boston: The sensitiveness of shocked and exsanguinated soldiers to anesthesia is a very interesting as well as important point in war surgery. If you talk to a surgeon about operating on a shock patient he will tell you he does not wish to touch the man on account of the danger involved. This hesitancy is due to the fact that the blood pressure falls to a perilous extent during the surgical procedure. In a series of cases we studied we found that the blood pressure fell during operation from 88 systolic down to 62, and from 62 diastolic down to 31, a calamitous drop when one considers that the pressure was already so low as to be barely enough to keep the tissues properly supplied with oxygen. Accompanying this fall was a marked drop in the carbon dioxide content of the plasma. It was found in the laboratory that these imperiling symptoms during operation were largely due to anesthesia. Animals were used experimentally to test out the effects of several anesthetics on shocked conditions. Under ether there was an invariable

and marked fall in blood pressure. Under nitrous oxide-oxygen anesthesia the effect depended on the relative amounts of gases in the mixture. In a ratio of 0:1 the effect of nitrous oxide-oxygen was almost that of ether. Ratios of 5:1 and 4:1 also precipitate falls in blood pressure. However, with a ratio of 3:1 the effect on blood pressure becomes negligible. There is no doubt that nitrous oxide-oxygen is the anesthetic of choice in shock and hemorrhage, especially when given with the greatest possible admixture of oxygen. If morphin is previously administered, the amount of nitrous oxide in proportion to oxygen can be reduced greatly. Furthermore, many shocked soldiers are so dulled that they can be operated on in analgesia, and surgical anesthesia is not necessary. Under ether anesthesia there is a means of sustaining blood pressure, and that is to start transfusion or infusion at the beginning of the operation and let it continue gradually while the operation is going on. Pressure is thus held up to a proper level, the blood stream is kept going with no reduction in its rapidity, and the shocked soldier gets through the operation in much better shape than would otherwise be possible.

Experiences with Anesthesia in Thoracic Surgery in the War Zone

DR. HOWARD LILIENTHAL, New York: The principles observed in arranging an apparatus were to provide a flow of air, preferably from a foot bellows, to pass through an ether container, in varying quantity and to be carried to the patient's pharynx by means of nasal tubes. Provided precautions were taken to avoid pumping liquid ether into the patient's throat or allowing the ether in the container to become too cold from excessive air pumping, little difficulty was experienced with the apparatus, once those trained had caught the knack of administration. Of course patients had to be anesthetized to the surgical plane before making the shift to the endopharyngeal technique. After this shift it was only necessary for the anesthetist to carry as smooth and light an anesthesia as was consistent with the surgical procedure to meet the surgeon's demands. The endopharyngeal method of etherization worked well for all plastic operations about the head, face and neck and for extrathoracic work on the chest. At first it was doubted that it would suffice for intrathoracic surgery; but it was soon found that the amount of pressure that could be maintained within the pharynx with endopharyngeal anesthesia was quite sufficient to keep the lungs in any state of inflation desired and yet not to interfere with pulmonary movement. If anything, this method proved more flexible than endotracheal anesthesia and more practically serviceable.

Ether Analgesia by Inhalation for Minor Operations, Especially in War Surgery

DR. FRANCES HAINES, Chicago: This method was developed in U. S. Base Hospital No. 13 in France as a result of the very frequent need of producing analgesia or very light anesthesia for certain operative procedures. Nitrous oxide being unobtainable in this hospital center, and local anesthesia being unsuitable for handling many types of wounds, this method of ether analgesia resulted from the spur of necessity. Our surgeons called for a method safer than ether by mouth or ethyl chlorid mixtures and for an analgesia often lasting more than three minutes. Thorough preparation of the patient, both physical and psychic, is more important to the success of the analgesia than to the safety of the patient. Mild catharsis and restriction of food and liquids should be the same as before general anesthesia. A hypodermic of morphin and atropin, one hour before operation, aids materially in calming the patient's mind. The patient's confidence should be gained. A Schimmelbusch mask covered with two layers of fine wool stockinette is the preferable apparatus. A towel or gauze roll is in readiness for wrapping around the edge of the mask. The patient's eyes are protected with wet cotton. The mask is saturated with ether as in using the so-called "ether-rausch" and more or less rapidly approached to the patient's face, and after two minutes is surrounded by the towel. The patient is usually in an analgesic stage in four minutes, with or without complete loss of consciousness, but without excitement. Ether is administered continuously

to within a few seconds of the termination of the operation. Within a minute, as a rule, even though analgesia is continued for from five to ten minutes or longer, the patient will be awake and in possession of his faculties. Theoretically, this analgesic stage seems difficult and almost impossible to maintain; but in practice it worked out successfully in 95 per cent. of the cases in which it was attempted. The only contraindication to its use is in partially united fracture, which might be broken should the patient resist during the opening of a sinus or insertion of a drain.

Experiences of an Anesthetist at the Front

DR. W. S. SYKES, Cleveland: Ether was used most extensively on account of its convenience and comparative safety and its not entailing cumbersome apparatus. The Scotch surgeons in the British service clung to chloroform, and their results were excellent. Ethyl chlorid was used to a considerable extent in the British service, particularly for minor operations. Ether-oxygen was a favorite method at the front in serious cases, the oxygen from a low pressure tank being sent through a Shipway apparatus to provide a warmed ether vapor. Owing to the scanty supply of nitrous oxid it had to be reserved for most desperate cases, in which it certainly proved a life saver. Toward the close of hostilities when compact, portable American gas-oxygen devices and cylinders of compressed gasses became available, the nitrous oxid-oxygen technic, as demonstrated by American anesthetists at the front, won the favor of surgeons of all the allied armies. It gave promise, also, of obviating to a great extent postoperative pneumonia. While many penetrating wounds of the chest were operated on under local anesthesia or nitrous oxid-oxygen at the base hospitals, nearer the front we used the warmed ether vapor, occasionally modified with the admixture of chloroform. Ether vapor was found quite superior to the drop method in every respect. It also saved the surgical team from working in an ether-laden atmosphere, something very much appreciated when shifts continued for from twelve to fourteen hours. Morphine was withheld from those in severe conditions of shock, as it lowered their resistance in a marked degree. Even one-fourth grain of morphine may invite disaster in the presence of shock or hemorrhage. Chloroform was, of course, contraindicated in shock. Ether depression was dreaded after operations in the same circumstances, and nitrous oxid-oxygen proved the anesthetic of choice in this condition. It was found very dangerous to alter the position of patients on the table after anesthesia had continued for more than half an hour. Consequently, in cases of multiple wounds, the minor ones received first attention and then the patient was placed in a posture which would demand no further change. The wounded, fresh from the front, were subconsciously exalted and prone to excitement during induction. This exaltation disappeared rapidly and was observed infrequently at the base and not at all on the return to home hospitals. Five c.c. of chloroform as a single dose proved to be an invaluable method for transient anesthesia or analgesia for minor procedures. While spinal anesthesia was used to some extent in base hospitals, it was found to be especially dangerous in all patients showing a reduction below normal of the hemoglobin index. Consequently its utility was limited.

Ether Administration in the Upright Posture

DR. FRANK DYER SANGER, Baltimore: Complications under etherization are distinctly respiratory in character. Hence it would seem logical to operate on patients under ether anesthesia in the same posture in which conscious patients seek relief from respiratory embarrassments, such as cyanosis, dyspnea and apnea. The same proposition held true for patients with broken compensation, despite the time-honored theory of cerebral anemia. Even for artificial respiration the upright posture has all the anatomic and physiologic advantages, since in it all the muscles assisting in the respiratory act have their proper play. The position offers many advantages from the operator's standpoint. The exposure in nose and throat work is good, illumination is easy, and hemorrhage and oozing are less troublesome than in the recumbent posture. Less assistance is required. Ether

administered by any method in this posture is easy; not infrequently the anesthetist can act as surgical assistant as well. I have never had an ether death or serious ether emergency in twenty-two years, during which I have employed the upright posture constantly.

Spinal Anesthesia

DR. W. G. HERRICK, Montreal: At the Montreal General Hospital we use the following solution for spinal anesthesia: stovain 5 gm., and commercial glucose 5 gm., dissolved in 95 c.c. of physiologic sodium chloride solution. This solution has a specific gravity of 1.031 and a neutral reaction, and is kept in sealed glass ampules of 2 c.c. capacity. The dosage is regulated in accordance with the weight, age and vitality of the patient. The maximum dosage is 0.07 gm. of stovain or 1.4 c.c. of solution, and the minimum 0.01 gm. The injection is made in the third lumbar interspace under rigid aseptic precautions, after 1 or 2 drams of spinal fluid have escaped. The saline menstruum of the solution tends to neutralize the osmotic factor, and the glucose exerts a cohesive action to counterbalance the diffusible tendency, so that the high specific gravity will carry the solution to the lowest dependent portion of the cord. Consequently, the sitting posture, and a semiupright posture during injection and operation, are used for sacral anesthesia. The lateral posture with hips and head elevated is used for low abdominal operations. For operations below the level of the umbilicus, analgesia is checked when the xyphoid is reached by quickly lowering the hips to the level of the table. For upper abdominal operations the analgesia is allowed to ascend to the level of the fourth intercostal space. By continuing the elevation of the head and shoulders during operation and for six hours after shock, faintness, respiratory distress and depression symptoms may be obviated entirely. Spinal anesthesia is used most advantageously in diabetes, or for patients suffering from advanced cardiac, pulmonary or renal insufficiency. It eliminates the dangers of postoperative acidosis. Operative analgesia persists for a period varying from forty-five minutes to two hours. Stovain has been detected in the spinal fluid twenty-four hours after injection, and traces have been demonstrated in the urine seventy-four hours after injection.

AMERICAN PEDIATRIC SOCIETY

Thirty-First Annual Meeting, held in Atlantic City, N. J., June 16-18, 1919

(Concluded from page 293)

Ostogenesis Imperfecta-Congenita

DRS. H. M. McCLANAHAN and W. W. WILLARD, Omaha: A male child, 3 months old, presented this deformity at birth. Several fractures were present, including fractures of the forearm, thighs and legs. At the time the child came under observation, masses of callus could be felt in the shaft of the thighs, arms and legs. The Wassermann reaction was negative and the von Pirquet test was negative. The child died of exhaustion after being in the hospital about six weeks. So far as I could ascertain, this was the youngest case with a fatal issue reported in which a careful histologic study was made.

DISCUSSION

DR. JOSEPH BRENNEMANN, Chicago: We ordinarily think of these patients as being in a serious condition, yet I have seen one child apparently in perfect health. After having had some kind of nutritional disturbance, its arm became sore and it was found to have a flail joint. A little later the other arm became sore, and it was found that the four long bones of the forearm were broken. No more fractures occurred.

DR. L. EMMETT HOLT, New York: I recently saw a child who had a fracture at the middle of the tibia, and six months later a similar fracture on the opposite side. In another instance a diagnosis of scurvy was made because of tenderness over the bones, and roentgen-ray examination revealed typical fractures. It is apparent that the influence of heredity

is of some importance in these cases. This type of fracture has nothing in common with the green stick fractures.

DR. CHARLES HERMAN, New York: About half of these cases show a family history of fragility of the bones. It is probable that there is a hereditary factor, but it is not only the bones that are abnormal, but also the ligaments and other structures. Another feature in these cases is the blue sclera, which is present in about half of the cases, and that also shows that the condition is not a disease confined to the bones, but that probably all the tissues of the body are somewhat abnormal.

Do Calories Measure the Value of Food?

DR. HENRY DWIGHT CHAPIN, New York: Heat measurement is not always a safe guide for estimating food values. In practice, the tendency is to keep a table of caloric values and to lay out the diet by arithmetic. The physician is likely to think that the caloric count is correct and that when he has met the caloric requirements the food problem is solved. Nutrition is not a simple oxidation process. In the animal body, energy resulting from chemical combinations may be converted into other forms without passing through the form of heat. Foods must be selected for their right physiologic value for each individual.

DISCUSSION

DR. FRITZ B. TALBOT, Boston: Physiologists are agreed that conclusions drawn from observations made on animals cannot always be applied to living children. I cannot agree that oxygen is not necessary in the presence of muscular contraction. It has been conclusively proved that every time a muscle moves the production of carbon dioxide is increased, and carbon dioxide cannot form without oxygen. The trouble that has come from caloric feeding in the past is due to lack of knowledge of the foundation on which it is based. Another factor is that some of the food calories are lost in the feces. Twenty per cent. of all protein taken in is consumed in making the remaining 80 per cent. ready for use in the body. The assumption that in using the caloric method of feeding one is using an accurate method is very inaccurate. The baby must first be fed what agrees with it and what it can digest. Second, the food must be well balanced. Third, one must see that the baby gets enough. I do not believe in any method of feeding; at the same time I do not think we should omit anything of value in determining whether or not a baby is getting what is correct, and the determination of calories sometimes helps.

DR. J. P. SEGWICK, Minneapolis: The estimation of the caloric value of food is a very valuable aid in determining the quantity of food an infant is getting. The determination of calories employed as a method of feeding is a great mistake. The estimation of the caloric value of food is not a method of feeding. One can feed protein or sugar or fat exclusively and still have the requisite number of calories; hence it is very incorrect to use the term "caloric method of feeding."

DR. F. W. SCHULTZ, Minneapolis: We should not discard the caloric measure of food altogether. It is about the only one we have for measuring the intake of food. It must be taken in connection with the tolerance for the different food elements.

DR. W. McKIM MARRIOTT, St. Louis: The caloric intake of food is subject to the laws of the conservation of energy and matter. When food is taken into the body it must be utilized in the processes of the animal organism or it must be stored. What is lost through the feces is as though it had never been taken. The difficulty in the caloric estimation of the food intake is that we have not estimated the amount used by the energy output. The error is in our method of making the computation and not in the caloric method.

DR. L. EMMETT HOLL, New York: Dr. Roche introduced percentage feeding, and by a misnomer it has come to be known as the "percentage method," in the same way the caloric measure has come to be known as the "caloric method." The estimation of percentages is exceedingly important. The caloric estimation of food values is of importance, but it is a method of statement and not a method of feeding.

Study of Stools of Institutional Children to Determine Existence of Intestinal Parasitic Infection

DRS. LAURENCE R. DEBUYS and H. L. DWYER, New Orleans: The study of 597 children in seven institutions shows that the frequency of the infections by the various parasites were in the order named: *Trichuris trichiura*, *Ascaris lumbricoides*, *Hymenolepis nana*, *Oxyuris vermicularis*, *Strongyloides stercoralis*, *Necator americanus* and *Hymenolepis diminuta*. The hygiene, general care, duration of residence in the institution, previous environment, association with dogs, eating of dirt, and absence of systematic medical inspection, seemed to have a direct bearing on the frequency of intestinal parasites. The symptoms usually attributed to "having worms" were as frequent, and some a little more frequent, in those not infected than in those infected. Eosinophilia is a valuable aid in the diagnosis of infection with intestinal parasites. It is, however, not pathognomonic, and its absence does not exclude an infection. The eosinophils were found as high as 28 per cent. in infected cases and 18 per cent. in negative cases. The diagnosis of intestinal parasitic infection is an extremely easy matter, the only way of making a positive diagnosis being by finding the parasite or the ova in the stool of the individual. Vermifuges should not be given to the child unless it is known that the infection exists and its character is ascertained, when the specific drug may be given to combat the particular infection.

DISCUSSION

DR. J. P. SEGWICK, Minneapolis: The medical profession is inclined to regard intestinal parasites as of less importance than do the laity. If we look for intestinal parasites, I think we shall find them much oftener than we have heretofore.

DR. JOSEPH BRENNEMANN, Chicago: Patients harboring *Ascaris lumbricoides* have come under my observation and have shown no characteristic symptoms.

DR. OSCAR M. SCHLOSS, New York: The symptoms depend on the grade of infection. In one instance a child had a very severe diarrhea with blood and mucus in the stools. These symptoms had persisted for a long time, and even after the infection had cleared up many ova continued to be found in the stools. It is a difficult matter to get rid of them, sometimes taking months of heroic treatment. The oxyuris may be present in great numbers without producing symptoms. Still has called attention to one symptom produced by this parasite, namely, pain in the right iliac region. I have seen several instances in which marked anemia was present in those infected with dwarf tapeworm; however, in proportion to the amount of infection, the symptoms are very slight.

DR. HOWARD CHILDS CARPENTER, Philadelphia: We had an epidemic of *Hymenolepis nana* in a foundling asylum in Philadelphia, where we made a careful study to determine, if possible, the mode of transmission. We trapped rats, but found them negative. It has seemed to me that the transmission was a direct hand to mouth infection. It is difficult to get rid of this parasite. Long after the parasites were no longer found in the stools, the ova were still present.

DR. W. McKIM MARRIOTT, St. Louis: In one case this parasite was found in the appendix. The boy presented the symptoms of appendicitis. The appendix was found to contain oxyurias.

DR. A. G. MITCHELL, Philadelphia: In France, many children are infected with *Ascaris lumbricoides*. Some of these children have acute symptoms which clear up when the infestation is eliminated. In some cases the worms have got into the stomach and the patients have complained of gastric symptoms; others have intestinal symptoms, diarrhea, etc. Whether or not the worms are the entire cause of the symptoms I cannot say; but the general nutrition of the children improves when the infestation is eliminated.

Glucose Tolerance in Atrophic Infants

DRS. H. F. HELMHOLTZ and L. W. SACER, Chicago: In these investigations the Woodhull apparatus and glucose manufactured by the Corn Products Company were used. The strength of the solutions was made approximately 10, 15 and 20 per cent. The actual concentration was determined polar-

scopically. It is immaterial, so far as tolerance is concerned, whether 10 gm. of glucose is injected in a volume of 10 c.c. or in a volume of 100 c.c., provided it is injected evenly in a given unit of time. If no sugar appeared in the urine in thirty minutes, glycosuria would not occur even after several hours of continuous injection. Injections were made in atrophic and in more nearly normal infants. The tolerance of those more nearly normal did not exceed 1.1 gm. per kilogram per hour, while the tolerance of atrophic infants ranged from 1.5 to 1.8 gm. per kilogram per hour. It appears that the sugar tolerance of normal infants does not differ much from that of normal adults. The tolerance of atrophic infants is considerably greater.

DISCUSSION

DR. OSCAR M. SCHLOSS, New York: In our experimental work we found that by increasing the sugar up to a certain point there will always be an increase of sugar in the urine, even though it is not sufficient to reduce copper solution. Another point of interest is that there may be considerable difference in renal permeability at different times.

DR. W. McKIM MARRIOTT, St. Louis: We have shown that atrophic infants can take large amounts of sugar. We have administered glucose by mouth and find that as much as 1.5 gm. of sugar per kilogram per hour can be given before glycosuria shows itself.

AMERICAN THERAPEUTIC SOCIETY

Annual Meeting, held at Atlantic City, N. J., June 6 and 7, 1919

The President, DR. DOUGLAS VANDER HOOFF, Richmond, Va.,
in the Chair

Indigestion and Gastro-Intestinal Disorders

DR. DOUGLAS VANDER HOOFF, Richmond, Va.: The term "indigestion" has become obsolete. This disturbance is a symptom and not a disease, and yet it is one of the most frequent complaints that brings the patient to seek advice of the physician. I have made a study of 1,000 cases in which the patients complained of "indigestion," and I have tabulated the causative factors. The most frequent cause was found to be chronic appendicitis (one fifth of all cases); together with gallbladder lesions, the causative factor in one third of all cases is accounted for. Peptic ulcer is the cause in one tenth of the cases; kidney and heart disease in one tenth; cancer in less than 4 per cent. of the cases; hypo-acidity in about one sixth of the cases. Miscellaneous conditions, such as pellagra, dysentery, lesions of tonsils and teeth, peritonal tuberculosis, and hypertrophic spondylitis were found to play a part.

DISCUSSION

DR. THOMAS F. REILEY, New York: Probably the last place to look for stomach symptoms is in the stomach itself. I think that two thirds of the therapeutic measures employed are in connection with stomach symptoms.

DR. JACOB DINER, New York: I am greatly interested in the statistics presented, particularly those dealing with kidney lesions as the cause of indigestion. There is often a nephritis present, usually the chronic interstitial or the parenchymatous kind. In New York City, in social work, 65 per cent. of all complaints are for indigestion. On investigation of the teeth, large pus pockets and alveolar abscesses are found, and if one can persuade these people to have their teeth looked after, the indigestion disappears of itself.

DR. OLIVER T. OSBORNE, New Haven, Conn.: Not enough emphasis is laid on the character of the food taken. One should not starve these patients, but undoubtedly many of them are eating wrong. Young people want to put two meals in one, that is, they drink milk as they would water with solid meals; that is putting too much work on the stomach. There are plenty of dietetic mistakes that the physician could stop, and thereby clear up the indigestion completely.

DR. F. M. POTTENGER, Monrovia, Calif.: The innervation of the intestinal tract and stomach is controlled by the sympathetics and vagus. Stimulation of the former produces inhibition; of the latter, increased activity of the muscle

and glands, and causes increased tension throughout the whole gastro-intestinal tract. This tension can produce the whole syndrome of appendicitis as well as that of hyperchlorhydria. The variability of the symptoms is because the stimuli do not explode in every individual alike. The profession has more or less discarded neuroses, but a large group of people are vagotonics, or perhaps the better term is parasympathetics.

DR. DOUGLAS VANDER HOOFF: We made the diagnosis of gastric neuroses with considerable hesitation. Many cases were organic and not functional. The functional cases were vagotonics.

Peripheral Irritations and Remote Results

DR. ROBERT T. MORRIS, New York: A child with a bean in the ear responds by nausea and vomiting, caused by the reflex irritations from the cerebral center. In loose kidney, the afferent impulse is sent to the cord center and the efferent impulse disturbs the sympathetic autonomic ganglions. Peripheral irritations lead into many misconceptions in practice because of difficulty in reading the true meaning of the symptoms. Peripheral irritations doubtless cause disturbances, any one of which may cause symptoms, while in the next case no reaction at all is produced by the same sort of stimulus. It becomes, therefore, a question of the character of response made by the patient. If we take as an example a strong, red-blooded man, with 100 per cent. hemoglobin, he will not respond to a peripheral irritation which would upset the sympathetic machinery of another person born with a narrow costal angle, with gunstock scapula, with relaxation of peritoneal supports, with high arched palate—in other words, with defective response and thus increased tendency to react to almost any peripheral irritation. With relaxation of peritoneal supports, with a sagging colon, dragging on the nephrocolic ligaments the kidney will get out of place and never get back again. This may or may not become a second step in the concatenation of the patient's distress. It may or may not send an impulse to the cord center which finds an efferent response, resulting in the disturbance of the entire gastro-enteric system. Disturbance of the digestive function step may cause fermentation and putrefaction on account of the involvement of the gastro-intestinal tract, and the poisoning may induce such a remote result as melancholia and manic-depressive insanity. One has to be particularly on guard against generalization.

Medical Treatment of Goiter

DR. GRANVILLE M. RYAN, Des Moines, Iowa: In treatment, the conditions must be clearly indicated. There has been no result as yet from efforts to find a counteracting agent for the thyroid toxin. Quinin hydrochlorid and salicylates have been used. Tincture of aconite is used to moderate the tachycardia. Attention must be paid to environment and hygienic conditions. Absolute rest, physical and mental, is an essential. An ice bag to the gland and small doses of bromid are indicated in acute exacerbations. The use of quinin and urea sometimes achieves good results. Use of the roentgen ray and removal of the tonsils are indicated in selected cases. The intelligent care of a good trained nurse is the most efficacious step in treatment, proper home care of these patients being practically impossible. In some cases the combined efforts of the medical man and the surgeon are necessary, the medical care preceding the operation, and supplementing it until recovery is complete.

DISCUSSION

DR. O. T. OSBORNE, New Haven, Conn.: No matter how many data the laboratory has furnished, nor how much is read on the subject, the results from therapy must be reached through clinical study. It may be necessary to give some drug, or a dose of a gland to test the case and find out whether the gland is hyperactive or hypo-active or simply absorbed. The rapid heart (130) without dyspnea is *always* of thyroid origin. Exophthalmic goiter is an attempt of the thyroid to counteract the effect of intoxication. Certain cases of this disease are improved by giving thymus. There is no question as to the necessity of rest, proper diet and the avoidance of irritating drugs.

Dr. F. M. POTTENGER, Monrovia, Calif.: By studying the patient physiologically, one gets a different attitude to that of experimental study. I am glad to hear that Dr. Osborne puts his faith in clinical observations, rather than laboratory work. There is a long way between a guinea-pig and a man. Clinical study requires the same care and close attention as laboratory work, and close observation will bring out many points.

Dr. H. C. GORDINIER, Troy, N. Y.: In early cases the patients recover with nothing but rest, plenty of fresh air and a lactovegetarian diet. Goetsch of Baltimore makes use of the epinephrin test which is a valuable addition to diagnostic methods in hospitals where the calorimetry method can be carried out.

Dr. H. C. Wood, Philadelphia: Symptomatic treatment has its place, for instance, in the control of the tachycardia. There are a number of efficient remedies for reducing the heart rate. *Veratrum viride* is as accurate as digitalis, and can be used while one is waiting for etiologic treatment to cause subsidence of the thyroid symptoms.

Dr. JOHN C. HEMMEYER, Baltimore: Professor Hamburger, president of the last international congress on physiology, in studying the increase of hyperthyroidism in the army in Holland, found it to be 10 per cent. Among the German people it was 8.5 per cent. It will soon be seen in this country in the nature of an epidemic, and preparation must be made to meet it. Ten per cent. of an army of a million means 100,000 cases. Are all these people infected? It would seem more like a physiologic process. The chromatolytic process does not necessarily mean intoxication. Why can there not be a thyroid neurosis, pure and simple?

Dr. W. F. MILROY, Omaha: During the hot season when the streams were dried up, a party of young people were daring each other to cross a ravine over a plank which was about 10 feet from the ground and had no supporting railing. One young woman made the attempt and got across for about 200 feet, when she got dizzy and fell. She was considerably shaken up, and when she came back collapsed entirely. She was assisted home. She immediately became ill and showed at once a markedly enlarged thyroid and marked exophthalmos with a very rapid pulse. She had never had any symptoms before, and was apparently in perfect health when she tried to cross the bridge.

Angina Pectoris

Dr. H. G. GORDINIER, Troy, N. Y.: Amyl nitrite and morphin sometimes give relief. Use of tobacco should be limited or prohibited; exercise and diet should be limited. Winters should be spent in the South. Treatment by nitrites is almost specific. Inhalations can be given with large doses of nitroglycerin, and then if no relief comes, morphin and atropin may be given to ward off vagus inhibition. Antisyphilitic treatment should be instituted when a positive Wassermann test is obtained.

DISCUSSION

Dr. DOUGLAS VANDER HOOK, Richmond, Va.: The figures in regard to syphilis mean more than mere statements. There is good reason to believe that 20 or 25 per cent. of cases are associated with syphilitic cardiovascular disease. Normal blood pressure, both systolic and diastolic, often exists for years in these cases. In regard to nitroglycerin, one surgeon who could not walk a city block without pain in his chest was enabled to carry on his surgical practice while taking nitroglycerin. Whenever it was necessary for him to walk he put a nitroglycerin tablet in his mouth. Angina is a syndrome, not a disease. Typical angina symptoms are seen in pericarditis in children, in myocardial disease, and in affections of the coronary arteries.

Dr. A. E. ROSSER, Philadelphia: The classical symptoms of intense anginal pain need not be accepted as the only major station. Although no deaths are caused by indigestion, many symptoms are caused by gas, which are the same type of disease. If these symptoms were recognized and treated, patients would live longer.

Dr. THOMAS F. REIDY, New York: There is often the danger of a patient's dying in a second attack, and for that reason the family should be warned of the danger. The

physician may give a morphin hypodermic and the family will blame him for the death of the patient. Morphine is of more use than nitrites in angina pectoris, but the attacks are often recurrent.

Dr. H. C. GORDINIER, Troy, N. Y.: I had one prominent patient fall down dead after the use of nitrite. It is a wise step to warn the family of the seriousness of the condition, before using morphin.

Rest in Tuberculosis

Dr. FRANCIS M. POTTENGER, Monrovia, Calif.: I tried the exercise plan. When I found it did no good I stopped it and tried rest instead, and began to get good results. The question of rest in tuberculosis must be based on something more definite than temperature. It is a question of conserving the patient's strength, and there should be enough energy left at the end of the day to take care of the normal demands of the day, plus the extra demands of the disease, plus reserve power. Fighting power must be conserved to the utmost. Rest and exercise must be applied in the right way. It is not enough to tell the patient to rest, as if he understood how it should be carried out. Most physicians understand very little of the minutiae of the rest treatment. Twenty-five per cent. more energy is required for rest in a chair than for rest in bed; sitting up and conversing requires 45 per cent. more energy. The difference between sitting up and lying down will turn the scale in many cases. Exercise increases the strain on the heart, already burdened by the effects of tuberculosis and the acidity of the blood, thus favoring breaking down of the enzymes, and autolysis. Every patient must be put to bed and kept there as long as there is any question of active tuberculosis. When the disease becomes quiescent, the patient begins to exercise by sitting up, perhaps for five or ten minutes at a time, increasing to twenty or thirty minutes, and then two or three hours. When he can sit up two or three hours without tiring, exercise is started, walking perhaps 50 or 100 feet a day. This graduated exercise means the rehabilitation of the patient, and brings him to the point at which he can walk from 2 to 10 miles a day without getting tired, and without toxemia. If one cannot do that, one has failed. Mental rest is of as much importance as physical rest. Rest and exercise must be adjusted to each individual. The sum of the matter is to treat by rest until the disease is inactive, and then to bring up exercise until the patient is well able to stand it.

Treatment of Influenza and the Pneumonia Incident Thereto

Dr. JACOB DINER, New York: There is no panacea and no standard method of treatment. The rule of treatment in our cases was subject to changes. Instead of digitalis, *veratrum viride* and aconite, and sometimes nitrites were used. The patient was put to bed in a properly ventilated room, without extremely cold temperature; 70 F. was considered advisable. Warm baths and good covering were provided. Ten grains of quinin and Dover's powder were administered at once. Hot lemonade, whisky and hot water bags to the feet were used. Hot drinks were used as long as the patient was awake, to provoke copious sweating. After twenty-four hours, an alcohol rub and change of sheets was ordered. No other food than milk was used. Caseara was used for the bowels. Nausea and vomiting were avoided on account of the weakening effect. The patient was kept in bed for seventy-two hours after return to normal of the temperature, pulse and respiration. Nourishing food was given at frequent intervals. Attention was paid to blood pressure and, in cases below 110, epinephrin, from 3 to 5 drops of a 1:1,000 solution, was found useful. With persistence of temperature, the case was considered as a potential pneumonia, and quinin and Dover's powder were continued. If râles were heard, hot flaxseed poultices were used every half hour. Digitalis and epinephrin were used. If the patient appeared toxic, 10 c.c. of camphor and olive oil were used. This was later discontinued. If the sputum was tenacious, ammonium salts were given, from 5 to 10 grains well diluted. With liquid expectoration, codain was used. Pleuritic complications were treated by hot applications and strapping, in

necessary, aspiration and thoracotomy. The pleura was irrigated with saline solution. The patients were of the poorest class, those admitted to a charity hospital. Forty per cent. of those admitted died in forty-eight hours; 30 per cent. died within twenty-four hours. The total mortality was 24 per cent. of 642 cases. The mortality under 10 years of age was zero. The next lowest death rate was between 10 and 20 years. The highest mortality was in patients more than 60 years of age. The patients who died seemed to fail from deep, well marked toxemia.

Case of Full Term Ectopic Pregnancy. R. M. Rawls, New York.—p. 53.

Excessive Loss of Blood by Pregnant Women.—Williams' study concerning the amount of blood lost during the third stage of labor and shortly thereafter and its clinical effects, is based on observations made on 1,000 consecutive spontaneous full-term labors. In the entire series the average time elapsing between the birth of the child and the extrusion of the placenta was 15.3 minutes, the extremes being spontaneous expulsion immediately following the birth of the child and a difficult Cr  d   expression at the end of ninety minutes. The average bleeding was 343.7 c.c. with the extremes varying from zero to 2,500 c.c., the placental period having been entirely bloodless in two patients. Less than 300 c.c. were lost in 527 cases. Only forty-six patients lost more than 900 c.c. of blood, and 100 lost less than 100 c.c.

Early Ectopic Pregnancy.—Heaney urges that every patient presenting herself with the suspicious symptoms of a threatened, imminent or incomplete abortion should be examined with the possibility in mind that she may have an ectopic pregnancy, more especially if the cramps are located in the side of the pelvis instead of being over the uterus.

Nourishment of Pregnant Woman.—Davis says that especially valuable in pregnancy are the earthy salts and fruit acids contained in vegetables and fruits. Vegetables furnish abundantly substances needed in the development of the skeleton, while fruits and fruit pulp and fruit acids are the best possible laxatives for a pregnant patient and if used with a free supply of water they rarely fail to maintain the action of the bowels. Where indigestion is annoying and persistent, especially valuable is the juice of the fresh lime and also that of the fresh pineapple. Acidity and gastric

indigestion may be annoying the patient and lead her to believe that she cannot take acids in any form. In estimating the diet of pregnant patients, the very important part played by water must not be forgotten. At least 1 quart of good water is required in twenty-four hours, and if the patient's metabolism is deficient a mildly saline water will prove of great benefit, but the mistake must not be made in cases where metabolism is deficient, of having the patient drink water in such excess that the kidneys are overcome and cease their function. Fresh air as a means of nourishment is of special importance to the pregnant patient.

Disease of Appendix and Pelvic Organs.—The results of a study in 746 cases are given by Child. He believes that disease of the pelvic organs in the female is an important exciting cause of appendicitis, and to a lesser extent the appendix may be a cause of right adnexal disease. In by far the greater number of cases of coexistent pelvic disease and appendicitis the primary source of infection is in the pelvis. Involvement of the appendix is nearly four times more frequent in right adnexal disease than in left. As the possibility of an involved appendix should always be borne in mind when operating on diseased adnexa, so also should the possibility of diseased adnexa be borne in mind when operating on the appendix. An appendix may be pathologic macroscopically yet not microscopically so, and vice versa, and should always be removed, if possible, when the abdomen is opened. Appendicitis in the female is associated so frequently with pelvic disease, that Child considers it to be a gynecologic condition.

Position of Navel of Man.—An examination of 1,000 persons convinced Niwase that there exists a typical geometric figure with reference to the position of navels. He measured the distance from the superior anterior iliac spine to the upper end of the middle line of the symphysis; from these two points to the under end of the navel and from its upper end to the inferior end of the processus xiphoides. In most cases the length between the navel and iliac spine, the iliac spine and the symphysis, the symphysis and the navel are quite the same; in other words, the navel exists on the vertex of the right triangle drawn, though not on a plane, but on an irregular spherical surface and stood on the line combining symphysis and superior anterior iliac spine, in 86.8 per cent. of the subjects. This geometric figure with reference to the navel, Niwase terms the umbilical right triangle.

Empyema in Children.—Churchill claims that empyema in children is relatively infrequent, developing in only about 5 per cent. of the cases of lobar pneumonia. It is gradual in

onset. In all cases of pneumonia, the possibility of its development should be borne in mind and the primary, original disease carefully studied. Its early diagnosis, with fluid small in amount, is often difficult; late diagnosis, with fluid considerable in amount, is easy. The diagnosis in infants and children is more difficult than in adults. Exact examination of the chest, performed daily, is often necessary to detect the condition. A displaced apex beat is an important diagnostic sign. In all cases of pneumonia where fluid in the pleural cavity is suspected, Churchill says, the exploring needle should be used, and if necessary, repeatedly.

Function of Chromophil Tissues.—It seems probable from Pearlman and Vincent's work that the chromophil tissue, especially, perhaps, the so-called "medulla of the suprarenal" may have important functions connected with the distribution of blood in the body, if not under normal conditions, at any rate in times of nervous and muscular strains.

Significance of Epinephrin in Muscular Activity.—In many experiments performed on perfused, excised muscles, the betterments were so marked and the vasoconstriction so striking that Gruber is convinced that only one conclusion can be drawn, i. e., epinephrin exerts some specific action on fatigued muscle other than that due to mere circulatory changes.

Action of Some Ovarian and Corpus Luteum Extracts on Pupil of Frog's Eye.—It was found by Macht and Matsumoto that the corpus luteum extracts, whether prepared from the fresh gland or from the desiccated product, produced a distinct dilatation of the pupil in from thirty to sixty minutes, depending on the concentration employed. Ovarian extracts, on the other hand, were found to produce very little or no change in the size of the pupil. Inasmuch as the ovarian preparations which were used contained small quantities of corpus luteum, the slight dilatation noted after the use of such extracts is ascribed to the lutein content. The difference between the effects of the ovarian and corpus luteum extracts, however, is so great that the authors regard the ovary and corpus luteum in so far as the effect on the pupil is concerned as being very different glandular bodies.

Leprosy. J. E. Lane, New Haven.—p. 387
*Treatment of Erysipelas. W. H. Guy, Pittsburgh.—p. 399

Chaulmoogra Oil in Leprosy.—In twelve years' experience in the treatment of leprosy, Hollmann has seen cases in which the manifestations of the disease have disappeared and the lesions become bacteriologically negative from the administration of chaulmoogra oil alone. Two patients subsequently had a recurrence of the disease, one within seven months, and one within two years. Twenty-six patients were treated with fractions of the fatty acid isolated by Dean from chaulmoogra oil. Hollmann is convinced that these fractions are superior to chaulmoogra mixtures. They are administered more easily, a much smaller dose is required at each injection, and there is more marked and more rapid amelioration of the disease. In the use of the ethyl ester of these fractions subcutaneously, the authors have noticed reactions in the leprosy lesions. In six months' time large nodules have entirely disappeared, leaving deep crater-like scars. Of the twenty-six patients treated, seventeen showed marked improvement; one patient showed slight improvement and only three patients showed no improvement, being under treatment only three months or less. Of the twenty-six patients treated, eight have become bacteriologically negative in less than two years.

Treatment of Erysipelas.—The usual applications were used by Huy from time to time, but boric acid solution is his choice. The general treatment was largely symptomatic. A polyvalent antistreptococcal serum was used in all cases; and 75 per cent. of the cases were influenced favorably. Amelioration of symptoms was too closely connected with the administration of serum to be explained on any other basis. An abortive effect was obtained in two cases seen and injected within the first six hours of the infection. In the majority of cases following the administration of serum there was a fall in temperature, pulse rate and respiration, followed in the course of a few hours by a slowly mounting temperature, which, however, usually did not reach its original height. At the same time the toxemia was lessened and patients were comparatively comfortable. Second and third injections usually acted in the same way, to the end that the course of the disease was in many cases probably shortened, and in most cases certainly modified as to severity. In about 25 per cent. of the cases serum seemed to have absolutely no effect, and in the majority of cases no particular reason could be assigned for this failure of therapy, but two cases were probably accounted for by reason of general debility, one patient having been in bed for some months as the result of a gunshot wound and the other suffering from pulmonary tuberculosis.

- *Studies in Osmotic Pressure. I. Mechanism of Boric Acid Hemolysis. M. Kosaka, New York.—p. 35
*II. Nature of Osmotic Pressure. M. Kosaka, New York.—p. 491

Mechanism of Boric Acid Hemolysis.—After blood corpuscles have been treated for a short time with certain concentrations of boric acid that are not directly injurious to these cells, the sudden immersion of the treated corpuscles in physiologic solution of sodium chlorid causes their complete hemolysis. This "boric acid hemolysis" Kosaka found does not occur if the addition of the physiologic saline solu-

tion is made gradually or if the corpuscles are immersed, even suddenly, in more concentrated solutions of sodium chloride or of other nonhemolytic substances. That the destructive force responsible for this form of hemolysis is that of "osmotic pressure" is shown by the fact that the minimal nonhemolytic concentrations of all of the substances examined were found to be identical "osmotic concentration."

Nature of Osmotic Pressure.—The results of the experiments made by Kosakai support the conclusion that osmotic pressure is not a direct property of a solute but is solely the pressure exerted by water which has passed, by the yet unexplained process of diffusion, through a semipermeable membrane to the side of the higher osmotic concentration.

Hemolytic Streptococci in Throat and in Erysipelas.—Streptococci isolated from the throat and from erysipelas exudate during the epidemic of the winter of 1917 and 1918, appeared biologically identical and highly virulent as based on criteria mentioned by Lucke and Rea. Their study confirms the observations of others, using immunologic procedures, and gives additional support to the belief that the streptococcus carrier state is an indication of the possibility of complications in respiratory tract diseases.

Serum Studies in Influenza.—The general results of the study made by Kolmer indicate that antibodies and particularly the complement fixing body, are developed in the serums of most influenza patients for *B. influenzae* and to a lesser extent for hemolytic streptococci and *M. catarrhalis*; similar studies were not made with pneumococci. These results, however, cannot be interpreted as an indication that the bacillus of influenza is the primary or chief cause of influenza inasmuch as this bacillus very probably possesses in the majority of cases sufficient pathogenicity to stimulate antibody production as an organism of secondary infection; similar studies with the streptococci of scarlet fever and the micrococci of acute anterior poliomyelitis indicate that what are very probably organisms of secondary infection, may stimulate specific antibody production. In general, the results of this investigation indicate on the basis of antibody production by the various organisms studied, that the bacillus of influenza produces most antibody during the course of the disease, and if this bacillus is not the actual or primary cause of the infection it is at least the chief organism of secondary infection, with streptococci ranking second in antibody production and importance.

Effect of Foreign Protein on Kidney.—The purpose of the investigation made by Bell and Hartzell was to determine whether chronic nephritis can be produced experimentally in rabbits by a foreign protein. Repeated shock was produced in a few animals, but in most of the experiments no attempt was made to produce anaphylaxis. Nontoxic foreign proteins, such as ascitic fluid, do not produce renal injury of any kind in the rabbit when injected intravenously in moderate amounts. The repeated production of anaphylactic symptoms with this protein likewise does not injure the kidney. Egg albumin may produce slight parenchymal injury when injected in large amounts, but usually it causes no damage. Toxic

foreign proteins such as sheep serum produce considerable parenchymal injury to the kidney which in some instances seems to lead to the rapid development of a renal infection comparable in all anatomic respects to the ordinary type of spontaneous nephritis. The fact that streptococci were isolated in pure culture from the kidneys of such animals shows that the lesion is essentially infective, and not the direct result of foreign protein or anaphylatoxin. No lesion comparable to human chronic glomerulonephritis has been produced experimentally. There is no experimental evidence that foreign protein is in any way responsible for chronic nephritis in man.

Spontaneous Nephritis in Rabbits.—Bell and Hartzell claim that the investigators who believe they have produced chronic nephritis experimentally have not had controls adequate to exclude the spontaneous disease, and the lesions described correspond closely with spontaneous lesions. No chronic glomerulonephritis has been produced experimentally. There is no anatomic or pathogenetic relationship between spontaneous nephritis in the rabbit and human chronic glomerulonephritis.

Protection by Filter Against Bacteria in Air.—Tests were made by Tolman et al. to determine the degree of protection offered by various filtering materials against suspension in air of *B. prodigiosus*. Buttercloth masks have been found to give inadequate protection against bacteria in this form. Felt is available which give complete protection against air borne bacteria of the size of *B. prodigiosus*. The portable electrical precipitation apparatus of Lamb gives complete protection against bacterial suspensions, killing the bacteria in its action. A mask with a felt filter with an area of 125 square inches and a pressure drop of about 1 inch of water has been constructed which will give complete protection. The efficiency of the buttercloth filter is greatly increased by wetting the cloth. It might be possible to arrange an efficient wet filter mask which would be much simpler, more comfortable, and cheaper than those in which felt is used.

Heart in Functional Cardiac Disorders.—A consideration of collected data in the light of physiologic facts Wiggers and Clough state makes possible the following conception as to the cardiac derangement in cases of functional cardiac disorders and at least certain types of compensated organic lesions: The normal heart possesses a mechanism whereby the systole is shortened when the rate is accelerated. This is especially evident when the rate increases beyond eighty per minute. The musculature, while subjected to more frequent periods of contractile stress, is automatically spared to some extent through a shortening of systole. In functional cardiac disorders, this compensatory mechanism (whatever its nature and cause) may be entirely abolished, or, what is more common, does not become operative until the heart has accelerated to a far greater extent (100 to 120 per minute). In other words, whenever the functionally disordered heart is accelerated above eighty per minute its period of systole is not shortened as is that of the normal heart and consequently the myocardium is exposed more frequently to prolonged period of contractile stress. This condition, favoring the onset of rapid cardiac fatigue is more serious since the hearts of these subjects are usually rapid even at rest. It appears that the same deficiency in the adjustment of systolic length to the duration of the cardiac cycle exists in many organic heart cases. Owing to the fact, however, that the heart rate in these individuals is usually slow, at least during rest and

moderate activity, the myocardium is in this way spared from the consequences of such failure to shorten.

Edestin Method for Estimation of Pepsin.—It is claimed by the authors that the method proposed for the preparation of edestin gives a product of sufficient uniformity to be used in the estimation of peptic activity without the necessity of ascertaining its exact edestin content. The procedure for determining peptic activity gives a clearer end point than that of the pea globulin method, is very practical for clinical use.

Journal of Pharmacology and Experimental Therapeutics, Baltimore

*Presence of Histamin (β-Iminazolyethylamin) in Hypophysis Cerebri and Other Tissues of Body and Its Occurrence among the Hydrolytic Decomposition Products of Proteins. J. J. Abel and S. Kubota, Baltimore.—p. 243.

Effect of Concentrated Salt Solutions on Output of Epinephrin from the Suprarenals.—Stewart and Rogoff found that intravascular injection of small volumes of concentrated salt solutions (sodium carbonate) causes a temporary increase in the rate of liberation of epinephrin from the suprarenals. They conclude that this increase is presumably due to stimulation of the nervous mechanism which governs the epinephrin output since it is accompanied by symptoms of a general excitation of the bulbospinal centers, and is not obtained or only in a minor degree, when even larger quantities of the carbonate are injected in more dilute form. The authors caution that in experiments on epinephrin output, it is not advisable to use concentrated solutions of salts in tubes connecting an artery with a mercurial manometer.

Effect of Nicotin on Output of Epinephrin from the Suprarenals.—The predominant and by far the most durable action of nicotin, whether administered intravenously or hypodermically, on the epinephrin output Stewart and Rogoff point out is a depressant or paralyzing action. The maximum diminution of the epinephrin output is rather rapidly reached and then there is a more gradual recovery, which when the dose is not too large, proceeds till the original output is approximately attained. At the time of maximum depression no epinephrin at all may be detected in the suprarenal vein blood by the test objects chiefly employed (rabbit intestine and uterus segments). The depressant action is preceded by a transient stage of excitation, lasting, as a rule, in these experiments not longer than from half a minute or less to a minute. In this stage the rate of epinephrin output is markedly increased (from two or three to ten or fifteen times the original output or even more, under our experimental conditions.) The latent period of the transient excitation, with intravenous injection of the drug, is very short. In some of the experiments there was evidence that it could not have exceeded a few seconds. The brief stage of excitation passes rather abruptly into the much more durable stage of depression. The maximum increase in the rate of epinephrin output is followed at a relatively short interval by the maximum depression of the rate, after which begins the gradual recovery. The changes in the rate epinephrin output are roughly parallel to the changes in the blood pressure caused by nicotin, indicating that when the sympathetic ganglion cells on the afferent vasomotor path are being stimulated or depressed, a corresponding stimulation or depression is being exerted on the efferent suprarenal secretory path. The nicotin effect on the epinephrin output is, speaking generally, the converse of the strychnin effect. The nicotin action develops more suddenly than the strychnin action.

Presence of Histamin in the Hypophysis Cerebri. Histamin, β-Iminazolyethylamin, a substance which stimulates plan muscle tissue in minute doses, which depresses the circulation, and which causes a shocklike prostration when administered in doses that lie beyond the limits of toleration, is a widely distributed constituent of all animal tissues, organ extracts and enzymatic products, whether derived from animal or vegetable proteins. Histamin,

according to Abel and Kubota, is a constituent of our diet and we daily consume no inconsiderable amount of the base, some of which is present in the form of the free base or a simple salt, while more of it is in all probability produced in the course of digestion. They suggest that histamin plays an important rôle as stimulant for the gastric and intestinal musculature and also as a dilator of capillaries during digestion, and that histamin is the most powerful¹ acting among the depressant substances which have their origin in mutilated tissues, and hence plays the leading rôle among the chemical factors concerned in traumatic shock. Histamin is the plain muscle stimulating and depressor constituent of the posterior lobe of the pituitary gland.

Osseous Abnormalities of Foot which Cause No Discomfort.—Pirie reports two cases in which pain in the foot was caused by the fact that the scaphoid of each foot had been developed from two centers, and the parts remained distinct.

Unusual Case of Torticollis.—A man was grazed on the back of the shoulder by a piece of shrapnel. A typical and well marked torticollis developed at once, lasted for a week, and then gradually passed away completely. On roentgen-ray examination, the second and third ribs were found to be fractured near their vertebral articulations; the seat of the fracture in the second rib corresponding to the attachment of the scalenus posticus muscle. Salmon concludes that the torticollis was, no doubt, due to the head and neck being involuntarily held in the position of greatest rest to the scalenus posticus muscle, and, perhaps, in a lesser degree, to one or other of the deep seated muscles of the back, and its extension into the neck; in other words, it was Nature's method of keeping the fracture at rest while it was uniting.

Diagnosis of Tuberculosis by Complement Deviation Method.—Wang and Crockett use a tubercle antigen which is essentially the bodies of the tubercle bacilli after their fatty substance has been removed. The syphilitic antigen is an alcoholic extract of the human heart, with or without the addition of cholesterol. The patient's serum is collected as for a Wassermann test from an arm vein with a needle. The blood suspension is prepared from defibrinated ox blood, which at the final washing should be spun at a fixed speed for a definite time, so that approximately the same thickness

of blood is obtained each time. The complement used is that of guinea-pig serum from 4 to 18 hours old. This investigation deals with the examination of serums from 104 tuberculous subjects and 220 controls. Of the tuberculous, in fifty-seven cases tubercle bacilli were found in the sputum, and in forty-seven they were absent. Altogether forty-nine patients had received tuberculin treatment at one time or another. The controls were 100 positive and 100 negative Wassermann serums, and of twenty serums taken from persons clinically known to be free from tuberculosis. The findings of the cases investigated, therefore, furnish 85 per cent. positives out of 104 tuberculous subjects. As none of the controls reacted positively to the test, it may be justifiable to regard the test as specific, and where a reaction is provoked a diagnosis may safely be pronounced, not only that the disease is present, but also that the lesion is in an active condition. Here, as in the Wassermann test, a negative finding is significant, though inconclusive. The nonspecific reaction which other observers have found was due, the authors suggest, to the presence of lipoids in their antigen and, in part, also to the tested serums being insufficiently heated.

Cure of Multiple Warts on Face.—The use of a saturated alcoholic solution of salicylic acid followed by abscission was surprisingly effective in Ind's case. The warts and skin around were painted three times a day for one day with this liquid. On the following morning the warts were cut off by a flat sharp steel instrument, bevelled on one side only; this passes freely over the healthy skin, but when it comes to the wart it is cut off, leaving a slightly bleeding point. The surface is painted at once with the salicylic solution and twice more later during the same day, three times in all. This turns the little red points a brownish black color, tiny scabs form which are allowed to drop off, taking about a week to do so, and leaving a perfectly clear healthy skin. The forehead is bathed with pure alcohol once a day until the scabs have all dropped off. There is neither pain nor scarring, and sepsis does not occur. The treatment is useless for larger warts. The use of the salicylic solution prevents pain when the warts are cut off and also prevents recurrence afterward.

With the 1st Lowland Field Ambulance in Gallipoli. G. H. Forster.—p. 30.

Phenomena of "Serum Disease."—A study by Davidson of the clinical and statistical differences between the three types of rash noted in serum disease has disclosed that these rashes differ from each other: (a) in their clinical appearances and manifestations; (b) in their relative frequency of occurrence; (c) in their minimum and maximum incubation periods and in the length of the interval of time between these two points; (d) in their average incubation periods; (e) in their order of occurrence; (f) in the character and course of their graphs; (g) in their duration. The relative frequency of occurrence of the three types is urticarial most, morbilliform less, and circinate least frequent. The order of occurrence of the three types is urticarial first, morbilliform second and circinate last. These findings suggest the possibility of the cause of each type of rash being also different and distinct. The distinction between the three types of rashes becomes even more marked in an investigation of some of the accompanying symptoms of "serum disease," and the theory that the causal factor in each type is not the same but of different origin is considerably strengthened. The most important accompanying symptoms are pyrexia, joint pains, edema, enlarged glands, and increase in the cardiac dulness.

*Studies on the Nature of Anaphylactic Symptoms Caused by Repeat Intravenous Injection of Asphenamm and Its Prevention. A. Hirano.

Nature of Anaphylactoid Symptoms Caused by Repeated Intravenous Injection of Arsphenamin.—On the basis of Millian's report that he had successfully prevented the development of anaphylactoid symptoms by the previous administration of epinephrin, and by his experience that it may develop severely in a patient having involvement in the suprarenals, such as a thymiclymphatic constitution or Addison's disease, Hirano concluded that there must be some intimate relation between arsphenamin and the suprarenal. The results of various experimental studies showed that by the administration of arsphenamin there occurs a sudden consumption of epinephrin in the circulating blood and the consequent supply of the deficit may not always be effected by the suprarenals, when anaphylactoid symptoms develop. This conclusion has been drawn from the following facts ascertained by experiments: 1. Arsphenamin anaphylactoid symptoms may be prevented by the previous administration of epinephrin. 2. Arsphenamin and neo-arsphenamin interrupt, to a certain degree, the epinephrin sublimate reaction *in vitro*. 3. The blood serum of the animals that received the intravenous injection of either arsphenamin or neo-arsphenamin contained a smaller quantity of vasoconstrictive substance than did the normal serum, if the serum was prepared from the blood withdrawn immediately after the injection of arsenic compounds. 4. The epinephrin content of both suprarenals decreases after the injection of arsphenamin. 5. A slight increase of the epinephrin content of the suprarenals was noted in rabbits that had been treated with repeated injections of arsphenamin. If a therapeutic dose of arsphenamin be given to the animals that had been thus treated, no remarkable decrease of the epinephrin content would ensue. But if the previous treatment was made with neo-arsphenamin, the epinephrin content of the suprarenals would indicate a remarkable decrease.

*Totsugamushi Disease. Results of Investigation during 1918. N. Hayashi, Mito-awara, and Oshima.

Tsutsugamushi Disease.—The authors collected as many specimens as possible from one infected region examined them and found that there are three different forms of the infecting organism. Only one form was found to give infection to the host. The mites are not only found infesting the field voles but also domestic fowls and a bird, *Acrocephalus orientalis*. The fact that these birds harbor the mites is a very important fact to know. This fact alone will make the elimination of the source of infection most difficult. It will also favor the distribution of the disease to a wider region. The field voles that harbor the mites live in a very restricted region along the rivers, while the bird has a wider habitat. The prevention of the disease has been experimentally carried out. The method consists in (1) the use of overalls in the field work; (2) the disinfection of the soil, and (3) the application of chemical preparations, especially insecticides to the exposed parts of the skin. By the use of the overalls and the insecticides, good results have been obtained, but the disinfection of the soil is very difficult to attain. The best way of extirpation of the infection seems to consist in the use of the overalls and the insecticides and the extirpation of the hosts or the akamushi, i. e., the field voles, the birds, etc.

Acquired Cranial Deformity.—Among the Mombetta tribe of Bantu stock, which lives in the Haut Uele district of the Belgian Congo the mothers artificially deform their infants' heads. It is their custom to compress the child's head by tight bands made of fiber. As the little skull grows it assumes an elongated shape. This deformity remains when adult life is attained and becomes a distinctive feature of the tribe.

*Tuberculosis from a West Indian Standpoint. J. Geoghegan.—p. 56.

*Influenza Pneumonia: Bacteriology of Complications in Fatal Cases. O. Heath.—p. 58.

Streptococcal Infections of Septic Wounds at a Base Hospital.—Porteous suggests that, as a rule, it is not the circulating blood which is at fault in cases of streptococcal septicemia, and in all probability there is some deficiency in the local protective mechanism which allows access of the streptococci to the blood stream. It would seem to follow, also, that for the successful treatment of a case of septicemia the most essential element would be the thorough local treatment of the infected focus. It has been observed that when an infection has become circumscribed by the collection of leukocytes in the walls of the wound and by the other factors which operate locally in this connection, it is very difficult to graft a serious streptococcal infection on the wound. It follows from this that the utmost care should be taken in the first few days after the injury to keep out the streptococcus and to avoid any treatment which will inhibit the development of the defensive processes. In the after-treatment fresh tissue should only be opened up when there is a very urgent necessity.

Certain Organisms Isolated from Cases of Influenza.—In the course of an investigation of material derived from cases of influenza during the three waves of the present epidemic, when searching for Pfeiffer's bacillus, gram-negative, "Pfeiffer-like" bacilli were frequently isolated. They were not, however, hemophilic and grew rapidly and readily on ordinary agar. They have been isolated by Fry from sputum, post-mortem material and in blood culture. The organisms derived from the latter source were isolated from the blood of two German prisoners, out of four cases examined, at the commencement of the third wave of the epidemic in February, 1919. The camp to which the prisoners had belonged had escaped the two previous waves, but was overwhelmed by the present one, a large proportion of the prisoners being severely attacked. The organism was obtained in 2 per cent. glucose broth and appeared in twenty-four hours in the blood culture, as round or oval, gram-negative "yeastlike" bodies, from 3 to 5 microns long and from 2 to 4 microns broad. Subculture to agar produce gram-negative bacilli, varying in size from coccoid or coccobacillary forms to short filaments. The "yeastlike" bodies rapidly disappeared from the blood culture, and were replaced by clumps of gram-negative bacilli, in the neighborhood of which could be seen, in some cases, gram-negative amorphous masses, resembling the ruptured envelopes of the above mentioned "yeastlike" bodies.

Bacteriology of Influenza Pneumonia. Pneumococcal or streptococcal organisms were found by Heath in sixteen post-mortems; in two out of three serous fluids taken during life; and in nineteen out of twenty sputums examined bacteriologically. Emphasis is laid on the hemorrhagic and infective nature of the fluids found post-mortem. Attention is drawn to the high percentage of fatal cases which came from "low category" units.

*Bronchial Spirochetosis. G. Delamaré.—p. 526.

Ethargic Encephalitis.—Etienne's patient was a girl of 17 who suddenly developed diplopia and slept for three weeks. She then recovered except for slight facial paralysis. The spinal fluid seemed to be normal in every respect throughout. An elderly man about the same time suddenly developed delirium and high fever, then deep somnolence, with death the second day. Claude and Schaeffer's patient was a woman of 42 and the somnolence had followed a week of headache. Ptosis was complete, and the woman died in less than three weeks. The temperature was high toward the last but the spinal fluid was clear and under normal pressure. Necropsy disclosed lesions of acute encephalitis in the isthmus of the brain, lower portion of the bulb, and the opto-striate nuclei. The lesions closely resembled those of Wernicke's polyecephalitis except for the absence of hemorrhagic foci. Aside from the special seat of these lesions, they differed also in other respects from the lesions of ordinary acute encephalitis, particularly encephalitis following influenza, in which edema of the brain is the predominating lesion.

Serodiagnosis of Typhus.—The agglutination of the Proteus X was diagnosed in the forty cases of typhus reported.

Treatment of Hemothorax.—Weil and Loiseleur treat traumatic hemothorax by puncture and injection of air or nitrogen, and they expatiate on the advantages of this procedure, describing three illustrative cases. They consider it important to filter the air as the blood offers a good culture medium for germs.

Encysted Hematoma in Pleura or Lung.—Sergeant and Pruvost remark that they do not know of any systematic study of this subject that has been published. With roentgen examination such hematomas are readily recognized, and the history of a trauma or unexplained hemoptysis will give the clue. Otherwise chronic pleurisy or hydatid cyst may be suspected. In one of the three cases described, a boy of 9 had hemoptysis after long violent running; in another case there was a history of a contusion. The blood may be evacuated through the air passages or it may become permanently encysted; even after evacuation of the cyst the walls may be so stiff as to hamper the movements of the lung.

The Wassermann Reaction in Eruptive Diseases.—Laederich and Bory found in 20 cases of scarlet fever, 4 of smallpox and 13 of measles that these acute infections modify the blood serum in the same way that syphilis does, only less intensely and only for about two weeks at most.

Convulsions After Gassing.—The convulsions, loss of consciousness and rise in blood pressure that followed exposure to mustard gas all subsided at once after withdrawal of 500 gm. of blood. The case teaches the importance of determining the blood pressure and bringing it down to normal by venesection in certain cases, the other symptoms being likely to retrogress with this.

Meningococcus Septicæmia.—Lemierre was unable to detect the meningococcus in the blood, spinal fluid, throat or skin lesions, but the agglutination test cleared up the case and permitted effectual serotherapy. The infection induced intermittent fever and recurring eruptive phenomena, thyroiditis, epididymitis, orchitis and parotitis, with only a slight meningeal reaction. The fever every evening for four months suggested malaria. During the febrile attacks there were severe pains in legs and lumbar region, and in time there was some muscular atrophy in the legs, but there was never any Kernig sign or stiffness of the back of the neck and only occasionally was there any headache and then it was mild. The appetite kept good most of the time. Repeated bacteriologic examination of the blood was negative but a neutrophil polymorphous leukocytosis pointed to some bacterial infection.

Bronchopulmonary Spirochetosis.—Delamaré recalls that recurring hemoptysis is characteristic of this affection, as also the fetid sputum. Arsenic treatment gives good results in the cases not complicated with tuberculosis. Emetin does not seem to benefit.

*Cure of Neuralgia under Fixation Abscess. Roumaillac.—p. 250.

Infant Mortality in French Cities During the War.—Chambrelent relates that the infant death rate at Bordeaux had reached in 1910 to 1912 its lowest point, namely, 10.9 per cent, but during the war it gradually increased until it was 23.1 per cent. in 1918. At Toulouse a similar rise was recorded, from 11 to 21 per cent.; at Marseilles, from 11 to 17 per cent., and at Rouen from 19.6 to 25. At Paris, from 15.51 in 1913 the infant death rate progressively declined to 13.96 in 1918. At Lille it was lower than ever known before, dropping from 20 in 1913 to 15.4 in 1918. Calmette ascribes this to the fact that as no factories were running at Lille the women stayed at home with their infants, and as not a drop of cow's milk was obtainable during the four years of the war, breast feeding was universal. It was supplemented by the condensed milk furnished at first by the American and later by the Spanish-Holland relief board. Calmette in a recent report commented most favorably on the excellence of this system of infant feeding. Even on condensed milk alone there were no more of the gastro-intestinal disturbances to which from 18 to 21 per cent. of the infants formerly had succumbed. The infant dispensaries and well baby stations were maintained at Lille throughout the war as before. The infant death rate at Paris was also the lowest ever known there. Ample dairy facilities had been provided for the city, fearing a siege, and the children had first-class milk throughout. This was not done at Bordeaux and the high death rate among infants shows the penalty. Chambrelent extols the valuable work done by two institutions at Paris where needy pregnant women are given a home until ready for the Maternity. One of these institutions has provisions for the woman's bringing her small children with her. A third institution is open day and night to shelter any woman in need. He urges the necessity for similar institutions elsewhere.

Fixation Abscess Cures Neuralgia.—The woman of 34 in the case described by Roumaillac had had for five years agonizing right trigeminal neuralgia, the attacks often coming on several times a day, evidently from autointoxication. An injection of 1.5 c.c. of turpentine, old and yellow, was then made in the left thigh. It induced a violent reaction, almost a diffuse phlegmon, but the neuralgia stopped at once and there has been no recurrence during the four years since.

Influenza in Young Infants. C. Achard.—p. 163.
*Boarding Out Infants in the Country. P. F. Armand Dillie.—p. 166.
*Latent Meningeal Reactions in Inherited Syphilis. Evergne.—p. 172.

Congenital Stenosis of the Pylorus.—Marfan remarks that this anomaly is very rare in France and in all Latin and Slavic countries. The infants take the breast or bottle as if famished, but soon drop it and seem to suffer pain, and there is pronounced oliguria as the children drink little and vomit profusely. One infant in his service died the thirty-eighth day after birth with nervous symptoms suggesting the action of a poison formed in the stagnating stomach contents. The congenital stenosis may cause no appreciable disturbance for a few years and then, under some inflammatory swelling or spasm, the pylorus may become impassable for the first time at the age of 2, 3, or even 11 or 12. After excluding esophageal regurgitations and mucus or rumination, the differentiation from ordinary habitual vomiting is based on the shortness of the periods of relative relief, on the absence of alternating periods of constipation and diarrhea (common with habitual vomiting), and on the roentgen findings. Further evidence is afforded by the lack of improvement under ordinary medical treatment. If no benefit is apparent

in three weeks, operative measures should be considered. His illustrations of the pathologic anatomy of congenital stenosis of the pylorus show the futility of expecting benefit from medical measures alone with complete impermeability.

Athrepsia with Inherited Syphilis.—The defective development liable with inherited syphilis in the liver, pancreas and parotid is shown by examples with four illustrations. The profound changes found in these organs readily explain the imperfect digestion of these infants. Specific treatment must be begun very cautiously, with milligrams rather than centigrams, as some children with inherited syphilis cannot bear specific treatment.

Boarding Out Infants in the Country.—Armand-Delille describes as a model to be imitated the working of the Speedwell Society in New York, which makes a specialty of boarding out weakly infants in a village readily accessible from the city. Each of the villages has its unit of a resident physician and visiting nurse. The nurse takes to each infant daily its quantum of nursing bottles, adapted to its age and condition, one nurse for twenty infants being the ideal. The board money, \$14 a month, and the expense of the milk, \$5, and of the clothing and medicines, plus the salaries of the physician and nurse do not total over \$1.15 a day, which is less than it would cost to keep the child in the hospital in New York. This society has been at work for fifteen years, he relates, and has thus cared for 3,500 friendless infants, many of whom have thus found permanent homes.

Latent Meningeal Reactions with Inherited Syphilis.—Laverigne has done lumbar puncture on infants in Marfan's hospital service even when there was nothing to suggest meningitis. The findings in the infants and older children confirm the rule that with inherited syphilis any changes in the cerebrospinal fluid should be considered as demonstrative as any other symptom elsewhere, and should call for energetic treatment, mercurial and, if possible, arsenical, until the lymphocytosis has disappeared. The lymphocytosis and albuminosis testify that the nervous system has been touched, to a certain extent. A spontaneous cure is possible but it is folly to count on it. Complications may be developing which will entail destructive lesions that might have been warded off by treatment in time, repeated until the puncture fluid no longer shows lymphocytosis.

Epidemic Scurvy.—The severe scurvy affected suddenly and simultaneously sixty-three men in a body of 350. The clinical picture reached its acme the second day, and after this day subsided, as if by magic, regardless of the treatment or lack of treatment or dietetic conditions.

Encephalomyelitis and Lethargic Encephalitis.—Cruchet states that in nine months (1917) he encountered forty cases of what seemed to be a subacute encephalomyelitis. The lethargic encephalitis described by others seems to him to be the same disease. He gives the details of some more recent cases and reiterates that any connection with influenza seems improbable as his early series was before the pandemic was heard of. Probably the cause is not single.

- *Syphilitic Pott's Disease. A. Aimes.—p. 214.

Carbon Dioxide Snow in Treatment of Skin Lesions.—Lortat-Jacob extols the benefit from localized freezing of the tissues in treatment of certain skin affections, but he has abandoned the use of the carbon dioxide pencil as not ensuring precision in the application. He uses what he calls a cryocautery, the carbon dioxide snow being formed within it and then acetone is added. This dissolves the snow but does not reduce the temperature. Its advantage is that it allows a more perfect contact of the snow with the skin. An index shows the graduated pressure; the time can be estimated by the watch. He ascribes the benefit from this treatment to the intense modification in the circulation as there is no sterilizing action from it.

Mineral Waters and Sequelae of Enteritis.—Under the heading "Practical Hydrology" the *Progrès* is publishing a series of articles on the mineral waters and spas of France, and the indications for their use.

Syphilitic Pott's Disease.—Aimes discusses the points which aid in differentiating syphilitic from tuberculous caries of the spine. He suggests that the rarity of syphilitic Pott's disease may be due simply to blunders in diagnosis. It is rare with inherited syphilis; it almost invariably affects men, and the usual location is in the cervical vertebrae. Cases are known in which sequestrums from the vertebrae were expelled through the mouth. When syphilitic excrescences can be detected, the diagnosis is facilitated. The pain is not relieved by repose, as with true Pott's disease, and exacerbation of the pains at night is characteristic. The prognosis depends on the phase in which treatment is begun, before irreparable lesions have become installed. The complications may include paralysis, dysphagia, sphincter trouble or even sudden death as in four cases on record. Radioscopy may reveal osteophytes. Even if syphilis and tuberculosis are both present, the benefit may be great from proper treatment of the syphilis. Vertebral sarcoma is generally secondary.

- *Biologic Test for Active Tuberculosis Focus in the Human Body by the Response to Intradermal Injection of Auto-Crine. H. Wildholz.—p. 793.
- Etiology of Influenza. J. L. Burckhardt.—p. 809, Cont'n.

Biologic Test for Active Tuberculosis.—Wildholz reports that his research during the last year and a half and experiences with more than 200 persons have demonstrated that when there is an active process of tuberculosis the urine contains an antigen which injected by the Mantoux intradermal technic induces infiltration and redness. This does not occur with urine from healthy persons or in urine from persons with healed tuberculous processes. It never occurs unless the person gives a positive response to injection of 1:10,000 tuberculin, but it seems to occur whether the urine is from the person being tested or not, so long as he has an active tuberculous process anywhere in the body, in glands, peritoneum, lung, bones or elsewhere. Wildholz evaporates morning urine to 1:10, passes once or twice through a paper filter impregnated with 2 per cent. phenol, and then makes three sets of two injections on the arm, the two upper with 1:1,000 tuberculin; 3 or 4 cm. below this, two with 1:10,000 tuberculin, and the same distance below, two with a minute amount of the 1:10 evaporated urine. The response with an active tuberculous process is the same with the urine as with the diluted tuberculin, but the tuberculin response persists unmodified after the process has healed, while the urine response fades out completely. A similar response was never obtained in the non-tuberculous, not even in syphilis, influenza, etc., with the single exception that urine containing large amounts of staphylococci induced a reaction, so that the findings are not pathognomonic in certain cases of nephritis.

With this exception, this biologic reaction, he reiterates, may be depended on to reveal the tuberculous or nontuberculous nature of lesions, and will also disclose when they are healed. If the urine reaction persists after the clinical healing of the known process we can be confident that there is some other active process elsewhere.

The specific nature of the urine reaction is demonstrated still more conclusively by the fact that, after subsidence of the urine reaction, if an injection of 1:1,000 tuberculin is made nearby, the apparently extinct urine reaction flares up anew, the infiltration and redness becoming distinct again. This does not always occur, but it is frequent enough to testify to the specific nature of the urine reaction. He cites three cases of different types to show the reliability of the findings with this urine test. In one, a boy of 13, had for over a year what seemed to be a tuberculous process in the ankle region, rebellious to all treatment. The roentgen findings were negative, the process being apparently in the soft parts. The urine test was negative, and the operation finally revealed a wood splinter in the depths of the fistula. In another case the positive urine reaction was not heeded as the diagnosis otherwise was so obscure, but necropsy revealed the grave tuberculous process in the kidney. In another, the course confirmed the urine test which testified that the case was one of incipient pulmonary tuberculosis instead of the supposed stasis hemorrhages from the uncompensated heart defect. By comparing the urine response with the response to the tuberculin test, we can obtain better insight than ever before on whether treatment must be kept up or the patient can be regarded as clinically cured. He repeatedly obtained a negative urine reaction in women nephrectomized a year or a year and a half before on account of isolated tuberculous processes in that kidney. He has never yet noted this rapid subsidence of the urine reaction in men after nephrectomy for this cause, and he assumes this to prove that there is still some lingering tuberculous process, possibly in the prostate or seminal vesicles. If repeated urine tests fail to give a positive response, year after year, we may accept this as evidence that the tuberculosis has been radically cured. He warns that patients being treated with tuberculin may give misleading findings as the tuberculin passing into the urine might imitate the reaction. Wildbolz is now engaged in research on intradermal injection of other body fluids, the serum, pleural and joint effusions and cerebrospinal fluid, and with the ophthalmoreaction with the milk of tuberculous cows. He is physician in chief of the Insel-hospital at Berne.

*The Cerebrospinal Fluid during Malaria in Children. G. Genovese.—p. 737.

Echinococcus Cyst in Abdominal Wall. R. Vergato.—p. 750.

Influenza and Malaria. P. Castellani.—p. 754.

The Cerebrospinal Fluid During Malaria in Children.—Genovese reports the findings in the lumbar puncture fluid in ten cases of malaria in children. The fluid was found pathologic during the malarial attacks, the reaction to the meningeal irritation being both chemical, physical and cytologic. The albumin content is high but not to such a degree as in acute meningitis. There is usually more or less intense lymphocytosis and the chlorid content is increased, but this does not inevitably occur. In some of his cases the fluid was merely under high pressure, with high albumin content but no cells in the fluid, although the complete meningeal clinical picture was present. Rubino has reported (1914) a case in which a boy of 9 was taken suddenly with what seemed to be typical meningitis, fatal the twelfth day, with continuous high fever after four days in the hospital. The lumbar puncture fluid was clear but under high pressure, with 0.5 albumin and lymphocytosis. The necropsy revealed signs of pernicious malaria with hyperemia in the meninges. Genovese's experience has been that pathologic conditions are

present when there is more than one lymphocyte per cubic millimeter. In another case a child of 2 began to have irregular fever, vomiting and diarrhea. There were no clear meningeal symptoms but the fluid was under high pressure and contained 0.5 per thousand albumin, 8.2 chlorides, and a moderate number of lymphocytes. The blood showed malarial parasites, and prompt recovery followed under quinin.

Diphteria in Influenzal Pneumonia. D. Giamelli.—p. 788.

Paralysis Following Intracutaneous Injection of Quinin. G. Sabatini.—p. 792.

Spasmodia in Children.—Lozzatti in this review of present conceptions of spasmodia emphasizes the difficulty at times of differential diagnosis of convulsions. Electric tests will usually decide whether they are of spasmodic origin or not, but they cannot be relied on exclusively. One child with jacksonian convulsions developing suddenly presented the spasmodic response to the electric tests, but the course of the case soon revealed tuberculous meningitis. In another case the diagnosis of meningitis was disproved by speedy recovery with signs of influenza. In both, there was evidently a substratum of spasmodia. The latter affects principally young infants. He warns further that epilepsy in young children is generally atypical. Judging from the literature, children with spasmodia often display a tendency to neuropathies and psychopathies as they grow up. Chloral by the rectum is the most rapid and harmless treatment during spasms, with sodium bromid and calcium bromid at other times, and cod liver oil with phosphorus. Hot baths, a cold douche to the chest and back, then putting the child in a warm bed and rubbing him, and stimulation of the skin or nasopharynx in other ways are among the measures suggested for respiratory spasm; chloroform, not being inhaled, is of little use. Regulation of the diet is of prime importance.

*The Anergy Theory and the Predisposition to Infections. G. Galeotti.—p. 437.

*False Dextrocardia. C. Guarini.—p. 438.

*Osteomyelitis of the Jaw. B. De Vecchis.—p. 439.

Aortitis. O. Cantelli.—p. 440.

Peculiarities of Influenza in Istria. M. Giusetti.—p. 444.

Protection for Pregnant Women and for Infants. G. Cristalli.—p. 45.

The State of Anergy or Predisposition to Infections.—Galeotti defines anergy as the inability of the organism to produce antibodies. This may be because an invading infectious germ may destroy the antibodies as fast as they are produced; or it may render the tissues incapable of producing them; or it may absorb the antibodies and thus render them useless. He includes in the term antibodies, opsonins and bacteriotropins, that is, all the defense reserves of the body, and urges research along the lines of these three hypotheses for better comprehension of the predisposition to infections. Influenza seems the most striking example of a condition of anergy produced by some unknown virus which throws down the barriers against invasion by any germs which happen to be on hand.

False Dextrocardia.—Sclerosis of the lung with retraction of the entire mediastinum from pleural adhesions induced apparent dextrocardia in Guarini's case.

Osteomyelitis of the Jaw.—De Vecchis emphasizes that in every acute and subacute affection in the neck or face, the possibility of the origin in a dental lesion must be borne in mind.

*Treatment of Chronic Constipation. A. de Silva Mello.—p. 153.

Treatment of Chronic Constipation.—Mello reports that his experience with Rosenfeld's method of treating habitual constipation with an antidiarrhetic diet was not favorable (Rosenfeld's article on the subject was summarized in Apr.

JOURNAL, Jan. 25, 1915, p. 376.) Mello remarks that Rosenfeld's success in his cases was probably due to the fact that he happened on a series of cases of pschitt, hypotonic and rectal constipation or mild degrees of spastic constipation, all of which are likely to yield readily to almost any treatment. Mello's cases were the graver forms, with irritation of the intestine, and the antidiarrhea diet is directly contraindicated. He refers disparagingly also to Kellogg's article in THE JOURNAL, June 30, 1917, saying that no method of treatment can be applied indiscriminately to all cases of constipation. Kellogg's system is the exact opposite of Rosenfeld's, and yet, Mello remarks, each writer makes much the same claims of constant success.

Gaceta Médica de Caracas

April 15, 1919, 246, No. 7

*Vitamin and Syndiotics. J. A. Risquez, p. 69. Concluded in No. 8, p. 82.

*Relapsing Fever in Venezuela. B. Tejera, p. 72.

The Question of Deficiency Diseases.—In the discussion that followed Risquez' paper on vitamins and syndiotics, Razetti said that beriberi did not exist in Venezuela until it appeared in Guiana. It had been imported from Brazil, and it is now spreading through the country, from the south northward, and will undoubtedly reach Caracas in time. The populace in Venezuela are living with the same customs and the same food now as a century ago. How can this invasion of the country be reconciled with the assumption that beriberi is a diet-deficiency disease? Ayala stated that beriberi had been unknown in his region in past epochs but comparatively recently it has invaded the extensive region of the llanos and reached Del Tuy although there has been no change in the food of the inhabitants. Machado emphasized that polyneuritis is not inevitably beriberi, and that polyneuritis may be due to a number of causes. He had an epidemic of fifteen cases of polyneuritis in a garrison many years ago, but the ration never included rice. The fifteen men were sent to camp out, a mile or so away, and all promptly recovered, although the food supplied was the same. The general opinion of the meeting seemed to be in favor of an infectious element in beriberi.

Relapsing Fever. Tejera has had two cases of relapsing fever in persons from Trujillo, and he found that a certain tick which abounds there is capable of infecting rats with spirochetes which seem to be identical with the parasites found in the blood in relapsing fever.

*Albuminuria after Operations on the Nose. D. I. M. Barajas y de Aldecoa, p. 141.

*Parotid Infections of Milk in Treatment of Certain Eye Affections. B. C. Duran, p. 147. Cont'd.

*Blood Prothrombin in Arterial Hemorrhage. J. Hervada, p. 145.

Albuminuria After Operations on the Nose. Barajas was recently called in consultation in a case in which after rhinotomy, diffuse edema developed, from head to feet, with inter albuminuria. This latter gave the clue as he had encountered a number of cases in which albuminuria followed interrupting or operating on the nose. It is evidently a reflex action, and soon subsided. He theorizes to explain the cause of this reflex by way of the pituitary and medulla oblongata.

*Partial Fictitious Stimulating Gallstone Colic. Udaondo, p. 137. Cont'd. Colic. C. R. F. Chacabarro, p. 138.

*Partial Fictitious Stimulating Gallstone Colic. Udaondo, p. 137. Cont'd. Colic. C. R. F. Chacabarro, p. 138.

*Partial Fictitious Stimulating Gallstone Colic. Udaondo, p. 137. Cont'd. Colic. C. R. F. Chacabarro, p. 138.

Partial Fictitious Stimulating Gallstone Colic. Udaondo's patients were two women, also two of three years had been having intermittent, sudden pain in the right hypochondrium, radiating to the back and lasting for fifteen or thirty minutes. The pain was induced by a mild gallstone colic, and the location of the pain and the pains always terminated with diffuse abdominal pain and an imperious movement of the bowels. Radioscopy demonstrated accumulation of gases in the colon, especially at the angle nearest the liver. This pressed on the liver and elicited the intense pains. In one of the women bradycardia, attenuation of the corneal reflexes and spastic constipation revealed a tendency to vagotomy. Under atropin and strontium bromid, with complete change from starch food to a predominantly albuminoid diet, the symptoms all subsided. Small doses of castor oil were also given daily at first.

Arrhythmias.—Barlario here inaugurates a series of articles on arrhythmias. This one is accompanied with nineteen illustrations in the text.

Constipation from Pericolicitis.—Barlario reports the case of a syphilitic young woman with a tuberculous pericolic lesion which entailed constipation and recurring pains. The laparotomy showed the colon covered with membranes which were easily detached. Mercury and tuberculin were then given on alternate days and the young woman has been in good health since.

Progresos de la Clínica, Madrid

April, 1919, 7, No. 76

*Plastic Surgery of the Face. A. Cortes Lladó, p. 120.

*Mineral Waters in Disease of the Digestive System. B. B. Campos, p. 147.

Plastic Surgery of the Face.—In this third and profusely illustrated article, Lladó discusses reconstruction of the entire nose, of the lip, cheek, and chin, with extensive bibliography, including some recent theses on maxillofacial surgery.

Mineral Waters in Treatment of Chronic Digestive Disturbances.—In this second article by Campos, he classifies the various diseases of the digestive apparatus according to the indications for different types of mineral waters. He warns in conclusion that the use at home of mineral table waters may be dangerous, as they are usually taken without medical supervision or advice. Some persons take a certain mineral table water regularly for years. Even although it may have been advised by a physician to start with, conditions may have altered since so that the special mineral water used may be directly contraindicated. Mineral waters, he reiterates in conclusion, should never be regarded as beverages but as medicines, and their use at the spa or in the home should always be for reasonable indications. Although bottled water loses some of its radioactive and other power, yet it resembles the water as it comes from the spring closely enough for the indications for it to be practically the same.

Even when all indications and method of taking are correct, the water cannot be kept up indefinitely without risk of modifying the blood pressure, injuring the kidneys, and favoring production of calculi. Morbid processes, besides, are usually progressing or retreating, so that what may be useful in one phase may be directly harmful in another phase. For example, carbonated waters may give relief in cases of deficient secretion of gastric juice, as they stimulate the secretory function. But this action is directly injurious with hyperchlorhydria, whipping up the already excessive secretory function. He adds that 75 per cent. of those in Spain who suffer from stomach disturbances have hyperchlorhydria. Injury is also liable with dilatation of the stomach as the carbonated waters increase the distension. Another prevalent and injurious custom is to take a strong alkaline mineral water with the meal. This neutralizes the gastric juice and impedes digestion. Mixed with wine, the alkali in the water forms new compounds with the tartaric and other acids in the wine, and the mineral water ceases to be alkaline, while the alcohol content of the wine is not modified by the new chemical compound. Weakly mineralized waters are the true table waters where pure drinking water is not available or where the drinking water has no lime. Also for persons who are becoming demineralized, as in tuberculosis, rachitis, scrofula and pregnancy. Mixed with wine, they form a sodium tartrate which, being laxative, counteracts the astringent action of lime. On the other hand, persons inclined to gout, to gallstones and urinary stones should refrain from waters with mineral content, and use mostly distilled water. He gives a classified list of Spanish mineral waters to meet the various indications.

*Surgery at the National Medical Congress. A. Esquedo.—p. 242.

Bacteriology and Influenza. Id. J. Pesci.—p. 244.

*Radium and its Applications. Mme. Curie.—p. 254.

Influence of War Surgery on Surgery in General. R. dos Santos.—p. 256.

The Mineral Waters of Spain. F. Tous Bager.—p. 294.

Surgery at the Madrid Congress.—This entire number of the *Revista* is devoted to this national medical gathering, the first of its kind in Spain. It was described in the Madrid Letter, page 207. The borderland subject of gastric ulcer elicited an especially lively discussion between internists and surgeons, as also radiologic treatment of uterine cancer.

Radium and its Applications.—Mme. Curie described the three classes of rays discharged by radium and their action on the tissues. She prophesied that emanations would in time be used altogether, instead of radium itself, in treatment of malignant tumors, microbial and toxic lesions, roentgen-ray burns, etc., and for injections, and also in the form of natural mineral waters. Mme. Curie closed her address with lantern slides showing the primitive laboratory in a wooden building where she and her husband made the wonderful discovery of radium. It will be remembered that she has twice been the recipient of a Nobel prize; in 1903 with her husband (the physics prize), and 1911 to herself alone (the prize in chemistry).

Revista Española de Obstet. y Ginecología, Madrid

January, 1919, 4, No. 37

*Case of Pabiotomy. D. Agusti Planell.—p. 9.

Pabiotomy.—In Planell's case the severed pubic bone had to be stretched apart for a distance of 6 cm. to permit extraction of the living child at term, weighing 3,325 gm. There was no apparent injury from this and the episiotomy except a slight laceration in the lower portion of the anterior vaginal wall. He always delivers the child at once, and the comparatively easy and rapid delivery in this extreme case teaches anew, he declares, the superiority of pabiotomy over cesarean section in certain conditions which he defines in detail.

February, 1919, 4, No. 38

*Acute Ileus of Gynecologic Origin. Vital Aza.—p. 49.

*Pregnancy after Roentgen Modification of Uterus. V. Conill.—p. 56.

Acute Ileus of Gynecologic Origin.—In Aza's case the large left ovarian cyst had such a long pedicle that the cyst had crossed to the other side of the abdomen, dropping into the right iliac fossa, while its pedicle passed over a sagging loop of the transverse colon and had strangulated the latter.

Pregnancy After Roentgen Treatment of Metritis.—The woman of 40 had been married at 17 and had had the uterus curetted at 25 for menstrual irregularities. The irregularities had persisted and at 40 the menorrhagias were so severe that roentgen treatment was commenced. The uterus was very large, reaching above the umbilicus, apparently the seat of diffuse fibromatosis or metritis with sclerosis. Four sittings were given, but the course then was interrupted by the epidemic of influenza, and when the woman returned again she was pregnant. She gave birth to a healthy child eleven months after the treatment had begun. It was the first child after twenty-three years of sterile marriage. Conill theorizes that the succulent, swollen lining of the uterus had impeded conception before.

*Puerperal Embolism. A. Franco.—p. 97.

Dysalimus Monster. V. Lobo.—p. 99.

*Contracted Pelvis. García Casal.—p. 101.

*Treatment of Cancer. E. Ribas y Ribas.—p. 105. Commenced in No. 37, p. 13.

Puerperal Embolism.—Franco discusses the factors which promote embolism, such as local interference with the circulation, the arteries working harder than usual, the veins suffering from pressure, etc. In addition to extreme care in warding off or correcting all such factors, he seeks to reduce the coagulating tendency of the blood by giving sodium citrate, and has found this a valuable aid in treatment of

phlebitis and embolism. He gives an intravenous injection of 200 gm. of a 5 per thousand solution of the sodium citrate in physiologic saline; if there is insufficiency on the part of the kidneys he uses distilled water instead of the saline. He repeats the injection daily for three days and after this on alternate days if it has to be kept up longer. The blood pressure rises, with diuresis, a chill and slight transient fever. He sometimes withdraws 300 gm. of blood beforehand. This treatment was a brilliant success in the two cases in which he has applied it. Later he read that sodium citrate was being given by the vein in cases of war wounds to aid in warding off phlebitis and thrombosis.

Contracted Pelvis.—García-Casal had planned to apply pabiotomy in the case described in which the pelvis was extremely contracted and deformed from rachitis and scoliosis. But owing to the unusually small size of the child it was delivered spontaneously in ten hours under expectant treatment.

Cancer.—Ribas emphasizes the existence of a precancer stage and the necessity for its early recognition. The blood with cancer shows acidosis, leukocytosis, high antitryptic and hemolytic power and reduction of the glycolytic ferment. He notes further that certain individuals are refractory to cancer, while certain families seem to display a hereditary predisposition to malignant disease although the hereditary transmission of cancer itself is denied by most authorities. In treatment of cancer he urges surgical intervention at the earliest possible moment but adds that remarkable cures have been realized with the roentgen rays and radium, also with vaccines or emulsions and autolysates. They might be supplemented with organotherapy when there is reason to assume liver insufficiency or endocrine upset.

Revista Médica de Chile, Santiago

February-March, 1919, 17, No. 2-3

*Acidosis and Surgery. A. Wall.—p. 55.

Spasm of Shoulder and Face Muscles. E. Malbran.—p. 59.

*Gonococcus Peritonitis. L. Vargas Salcedo.—p. 63.

*Trachoma in Chile. J. Thierry.—p. 70.

Acidosis and Surgery.—Wall reports some cases in which symptoms caused by acidosis were mistakenly ascribed to some supposed tumor casually discovered, or to the appendix. Operative treatment for the assumed tumor had no effect on the acidosis, the actual cause of the symptoms, except possibly to aggravate it. The surgeon may never learn of his blunder as when the symptoms persist or return the patient has no further use for the surgeon and hence does not return to him. In one case recently a young woman had been having general malaise for three or four days, intense headache, vomiting, and pain in the hypogastrum and right iliac fossa. The tenderness was diffuse and included part of the hypogastrum. This was her first alarming attack, but for some years there had been periods of diarrhea alternating with constipation. Called in consultation, Wall doubted the diagnosis of appendicitis that had been made, and called for examination of the urine for acetone. The acetone reaction was intense and the reaction for diacetic acid was positive. Under treatment of the acidosis with sodium bicarbonate by the mouth and rectum, the whole clinical picture rapidly subsided. If appendectomy had been done as proposed, the general anesthesia might have brought on fatal coma. He emphasizes that acidosis does not signify exclusively retention of acetone bodies. The essential element in it is the depletion of the alkali reserve in the blood. Starvation acidosis must be counteracted, and he makes a practice of combating postanesthetic disturbances by giving the alkali by the rectum and even by the vein. The results have been most gratifying in his long experience with this. In another case reported, a myoma in the uterus casually discovered was accepted as the cause of the symptoms, explained later as acidosis by examination of the urine. Tenderness from ovaritis contributed to mislead the physician to ascribe the whole trouble to the tumor. Of course acidosis does not exclude a possible surgical affection, but the possibility of acidosis should always be borne in mind.

Gonococcus Peritonitis.—Salcedo relates that the onset of gonococcus peritonitis does not differ from that of any diffuse

peritonitis, but the general condition keeps more favorable than with peritonitis of other origin; there is not so much vomiting or tympanism, the tongue is moist and the septicemia seems to be mild. The laparotomy shows that the primary focus is in the tube or ovary or both. The secretions do not have the usual fecaloid odor. He advocates operating at once, and reports two cases from his large experience. In one fatal case the gonococcus and streptococcus were associated, and the toxemia was intense.

Trachoma.—Thierry reviews his 136 cases of trachoma during twenty years of practice at Valparaíso. Trachoma is evidently becoming more prevalent, mostly imported cases. He urges stricter measures against its introduction into the country, saying that every thousand dollars spent now for this purpose represents the saving of a million later.

Revista de Medicina y Cirujía, Caracas

April, 1919, 2, No. 13

*Drainage of Seminal Vesicles. J. C. R. Morales—p. 205.
Dietetic and Medical Treatment of Bladder Calculi. A. Bonifetón—p. 273.

*Hookworm Disease in Venezuela. J. B. Ascanio Rodríguez—p. 282.
Peforation of Velum by Larvae of Fly. A. Petri—p. 288.

Drainage of Seminal Vesicles.—Morales explains how infectious processes in the seminal vesicles are liable to entail retention of secretions and of pus, and the necessity for evacuating them. He urges practicing the procedure on the cadaver, and expatiates on the fine results likely to be realized when this focus of insidious infection is cleared out. The best results are realized in cases with joint lesions; he reports that 76 per cent. have been cured in this rheumatic group and 23 per cent. much improved. In the group with local suppuration, 61 per cent. have been cured and 23 per cent. improved, but no benefit was apparent in 14 per cent. In the group in which pain was the main symptom, 60 per cent. were cured and 25 per cent. improved. In fully 25 per cent. in this group calculi contributed to the clinical picture. In the pus cases the suppuration usually involves the prostate and neck of the bladder. A radical cure can be anticipated only by resection of the vesicles and the prostate. Morales warns that the state of the sexual functions should be determined before any action on the seminal vesicles. Otherwise the physician might be held responsible for any preexisting abnormal conditions. In about 10 per cent. there is post-operative impotence, but this is transient. Chronic spermato-cystitis generally modifies the sexual functions. He describes in detail the Fuller and Squier methods for evacuating the seminal vesicles, saying that the former is generally regarded as difficult and dangerous.

Hookworm in Venezuela.—Rodríguez lists the numerous places where his patients had acquired hookworm, showing that practically the whole country is infested.

Revista de Medicina y Cirujía, Havana

June 27, 1919, 21, No. 12

*Encephalitis Monster. R. Fernández Valenzuela—p. 119.
*Seat of Sensations of Hunger and Thirst. J. L. Arceaga—p. 127.
Continued in No. 11, p. 289.

Encephalitis Monster. Valenzuela gives an illustrated description of a typical instance of this form of monstrosity. She accepts some anomaly in the amnios as probably responsible for the malformation.

Seat of Hunger and Thirst. This is the article which won the Gordon A. Costa prize for Arceaga. He discusses whether in the present status of our knowledge it is possible to determine the seat of the sensations of hunger and thirst, replying to his question in the affirmative. He explains that hunger and thirst are phenomena common to the cells of every living being as manifestations of the lack of chemical elements indispensable for the life of the cells. These trophic sensations of the cells may be unconscious in the lower animal. In they become conscious phenomena as the nervous system of vertebrates becomes more highly developed. In man, hunger is manifested by painful contractions of the stomach and thirst by dryness of the mouth and throat. These phenomena are purely reflex, the principal

centers for hunger and thirst being in the medulla oblongata, but Auerbach's plexus is also involved, especially in relation to hunger. He discusses in detail the phenomena from lack of lime, etc., in man, animals and birds, and the way in which amphibious animals change their diet as they live in water or air.

Revista de Psiquiatría, Lima

April, 1919, 1, No. 4

*National Problems of Mental Health. H. F. Delgado—p. 203.
Paraplegia of Traumatic Origin. E. Odriozola—p. 214.
*Question of Survival. I. Avendaño—p. 220.
Medicolegal Course. O. M. Quesada—p. 226.
Disability from Chronic Paranoia. H. Valdizán—p. 237.

Psychopedagogics.—Delgado discusses the inadequacy of the care of the insane in Peru, there being only one asylum, and this has accommodations for only a tenth or twentieth of the insane throughout the country needing institutional care. As an aid in building up a more rational care of the mentally deranged and, above all, for prophylaxis of mental derangement he, with Valdizán, has organized a four months' course for school teachers and others on the psychology, psychiatry, and hygiene of the child, neuropathology of the school, and the Montessori method.

Question of Survival.—A man and wife had been assassinated at night. The woman had been stabbed at twenty-three points while the man had been stunned and killed with heavy blows with a club. The assassin would not have ventured to attack the man in this way, Avendaño concludes, if the wife had not been already dead before the husband came in.

Semana Médica, Buenos Aires

May 13, 1919, 26, No. 20

Proposed Medical Curriculum. G. A. Alfaro—p. 503.
Pin in Child's Appendix. R. A. Rivarola and A. Sem—p. 506.
*Ferrán's Conception of Tuberculosis and Vaccine Prophylaxis. M. R. Giacomini—p. 507.
*Syphilomania. C. F. Gandolfo—p. 522.
*Urine as Antigen in the Wassermann Reaction. J. Baicigalupo—p. 523.
*Typhus. G. Giacomini—p. 529.
*Determination of Acetone in the Urine. P. B. Guggiani and G. M. Crovato—p. 532.

Vaccination in Prophylaxis of Tuberculosis.—Ferrán's conception of the tubercle bacillus as only the third phase in the life of the micro-organism responsible for tuberculosis has been already described in these columns. His later research has confirmed him more and more in his views and in the efficacy of vaccination based on them. The first stage of the micro-organism he calls the alpha stage. The bacillus then is merely an ordinary nontoxic saprophyte, but under certain conditions it induces phlegmasia and even galloping consumption but without tubercle production and without true tubercle bacilli. The second stage of the micro-organism corresponds to Much's granules, and the third stage is the true tubercle bacillus. The importance of this conception lies in the fact that by a vaccine prepared against the first phase, the nonacid resisting alpha bacillus, the system is immunized against it and thus the whole chain is broken up and it does not progress to the other stages. It is easy to cure this phase of pretuberculosis by the alpha bacillus vaccine, but once the second or third phase is reached and the true tubercle bacillus installed, vaccine treatment is impotent. Giacomini reiterates that the hopes based on tuberculin treatment of this phase have not been realized in practice.

Syphilomania.—Gandolfo reiterates that every person benefited by the salicylates is not inevitably rheumatic, and every person that improves under mercury is not necessarily syphilitic, as so many seem to think now. Syphilis is diagnosed at every turn, no matter what the history may be. He is convinced that we are passing now through a period of syphilomania.

Typhus. Giacomini relates that in infants typhus appears with an itching eruption, with phlyctenosis. The eruption subsides after the first few days in the grave cases. In older children and in adults, the eruption is of the petechial type. Another characteristic feature of the disease is the edema in the brain, and this is responsible for the cerebral disturbances

and is directly connected with the skin lesions, as the skin and brain are formed from the ectoderm. The cerebral symptoms or the skin symptoms may predominate; with the former he gives hot baths to induce revulsion to the skin, seeking to imitate the natural eruption revulsion. He has observed a complication of typhus not mentioned in the textbooks; this is a hemorrhagic process in the peritoneum at about the eighth day. This peritoneorrhagia with thready pulse, he says, calls for ice to the abdomen and deep injections of ether, under the rigid abdominal wall, injecting daily 3 or 4 cc. of ether. This aids in the resolution of the process, sterilizes, and wards off the otherwise almost inevitable purulent peritonitis. He repeated these injections daily for ten and fifteen days and the cerebral symptoms and the general condition rapidly improved. In conclusion he reaffirms the importance of the principle of relieving congestions and edema in the brain by inducing or promoting the eruption.

Acetone in the Urine.—Gaggiari and Crovato have modified the Imbert technic, as they describe, and commend their modification as superior to it for determination of the acetone in the urine.

Siglo Médico, Madrid

May 31, 1919, 66, No. 3416

*Roentgen Treatment of Hypertrophied Prostate. B. N. Cánovas.—p. 433.

*Strabismus. B. Castresana.—p. 434. To be cont'd.
*Nevi. Sierha.—p. 439.

Roentgen Treatment of Hypertrophied Prostate.—Cánovas emphasizes that benefit from roentgen exposures can be counted on only when the hypertrophy is of the glandular type of tissue. This may regress under the influence of large doses of hard rays. Notable improvement of all the symptoms for from six months to a year to date followed the roentgen treatment in his cases of this adenomatous group. He urges a tentative course of roentgen treatment in every case before operating on an enlarged prostate. The best results may be anticipated when the tissues are most sensitive to the rays, but this imposes extra caution as acute retention may follow too large a dose of the rays. More than a year has elapsed in four of his ten cases and the previous frequent attacks of retention have not returned. In one case the discovery of polyps called for operative measures. The pain disappeared in another case and the tenesmus, but one diabetic with bilateral hernia has not shown any benefit. The outcome is not known in another case. Cánovas does not give any details as to his technic, but he warns in conclusion that "catching cold," constipation and indigestible food are liable to aggravate conditions with an enlarged prostate.

Operative Correction of Squint.—Castresana resects the muscle and passes three sutures underneath the stumps, through the sclera and through the conjunctiva at each side of the wide crescentic gap cut in the conjunctiva. The central suture is horizontal but the two others curve outward, thus embracing more fibers of the sclera. As the threads are drawn up, this indirect advancement of the muscle corrects the deviation of the eye, and the stout adhesions which form render the correction permanent. The ends of the threads are fastened to the skin with plaster. The antagonist muscle can also be stretched through a linear incision. He emphasizes that the outline of the sutures taken in this way is that of a rhomboid, with the horizontal diameter longer than the vertical. The results have been extremely gratifying in the eighty cases in which he has applied this technic since 1915. As a rule he calculates resection of 2.5 mm. of muscle for 10 degrees of deviation. A number of cases are illustrated and the article is to be continued.

June 7, 1919, 66, No. 3417

*Tubes and General Paresis. E. F. Sanz.—p. 453.

Tubes and General Paresis.—Sanz regards as valuable innovations in treatment of syphilis of the nervous system the addition of mercuric cyanid, and its administration by the vein as also arsphenamin, supplemented by intraspinal infusion of arsphenaminized spinal fluid. The indications

differ with tubes and general paresis only in that the intravenous treatment alone may suffice for the latter, but tubes is rebellious to intravenous treatment alone. He protests against an inevitably pessimistic attitude in syphilis of the nervous system. Although a complete cure is out of the question, yet the clinical picture can be materially softened, especially when the diagnosis is made early. The progress of science has facilitated this with tubes, but we are not certain with general paresis.

June 14, 1919, 66, No. 3418

*Influence of the Prostate on Bladder Infections. P. Cifuentes.—p. 473.

Influenza. C. M. González.—p. 477.

Influence of the Prostate on Bladder Infections.—Cifuentes comments on cases in which cystitis was induced and kept up by an infectious process in the prostate. He reports in detail a case for which the colon bacillus alone seemed responsible, and in which the shadow of a phlebolith led to the mistaken assumption that a bladder stone was the cause of the bladder disturbances. The cystitis had flared up anew whenever the man "caught cold" or got chilled.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

*Oil Dermatitis. D. Broek.—p. 1488.

Lethargic Encephalitis in Adult. D. J. Beck.—p. 1494.

Miracles of Healing.—This was the presidential address delivered at the recent annual meeting of the Netherlands Medical Association. Nolen described in detail the case of a woman of 44 totally helpless from paralysis for ten months, which had developed gradually during the preceding three years. During several months' stay at a sanatorium she regained the use of her legs, but they became paralyzed again on return home. She had to be fed, and turned in bed, but had no fever. Nolen then passively exercised her joints and made her sit up in bed, making her continue this spontaneously, and improvement speedily progressed to complete recovery. He relates that he has had a number of such "miracles of healing," and compares them with similar miracles of healing on record through the ages. He emphasizes that these miraculous cures are not the work of supernatural, magic forces but of psychic measures within the reach of every one, but not to be picked up without effort. Of course there are some people so easily impressed and unreflecting that they respond to even the most blatant quack advertisements. But most sick persons do not want to have anything to do with quacks, and they place their confidence in regularly qualified physicians. The psychic measures which these patients require must be taught, must be studied over, thought out and adapted to the special case. One inconsiderate word may spoil everything. In the medical course the diseased mind is well studied, but nothing is taught of the workings of the normal mind. What would we think of a farmer sowing the seed for his crops without any knowledge of the conditions and nature of the soil! Body and mind are closely bound together and exert a constant interaction on each other, and the study of "miracles of healing" contains many a useful lesson for us.

Oil Acne.—Broek comments on the wide prevalence of acne, furuncles, pruritus, etc., in persons working in oils. He found reducing substances in the urine of four persons thus affected. This suggests that deficiencies in the diet may be the determining factor, an endogenous factor cooperating with the oil.

*Treatment of Oxyuriasis. H. Kjerrulf.—p. 401.

*Influence of the School on the Spread of Influenza. F. Zander.—p. 415.

Treatment of Oxyuriasis.—Kjerrulf comments on the wide distribution of oxyuriasis in all countries and in all classes, and relates experiences which demonstrate the inefficacy of tannacetum and other remedies which have entailed their venue.

He has been most successful with basic aluminum acetate, 1 gm. three times a day, given with a purgative of calomel, sulphur and compound licorice powder, administered for three or four days. To ward off reinfection, the anus is smeared with a salve containing 1 part thymol to 2 parts each of camphor and quinin sulphate in 30 parts lard. He has been using this combined treatment for eight years.

The School and the Spread of Influenza.—Comparison of the curve of influenza in and outside of a large school at Stockholm showed that the school morbidity closely paralleled the general morbidity. The figures seem to demonstrate further that influenza is not contagious during the first day. Consequently if children taken sick are sent home at once there is no need to close the school.

*Roentgen Study of the Duodenum, A. Akerlund.—p. 449.

Duodenal Ulcer.—Akerlund comments on the local spasm that may be induced by duodenal ulcer, and on the distant spasm which it may induce in the body of the stomach. The local spasm at the site of the ulcer explains some of the symptoms with duodenal ulcer. It occurs as often as spasmodic contraction of the stomach with gastric ulcer. A roentgenogram showing local constricting spasm in the bulb of the duodenum, accompanied by local tenderness, is convincing proof of duodenal ulcer, he thinks. This spasm causes a characteristic scalloped outline in the roentgen shadow of the upper duodenum; there seems to be always a round protruding bunch which represents the ulcer itself, the spasm nearly closing the lumen of the duodenum just above and below this knob shadow. The pylorus is generally wide open. This spasm of the region of the duodenal ulcer explains the initial hypermotility and the "paradoxical" four hours' retention, the spasm coming on gradually as digestion progresses, after the hypermotility at first.

The remote spasm in the stomach with duodenal ulcer may occur with quite normal conditions in the stomach. With roentgenoscopy he has witnessed this spasmodic contraction of the middle of the greater curvature of the stomach develop under his eyes when pressure was applied to the tender duodenal ulcer. This is a very important aid in the diagnosis of duodenal ulcer. He describes three cases of simultaneous gastric and duodenal ulcer, verified by operation in one case. The others are doing well under internal measures alone. He gives the roentgen findings also in some cases with a diverticulum in the duodenum. In one case it was associated with chronic pancreatitis. In another case a diverticulum near the duodenojejunal flexure was seen filled with air at first and later with the contrast suspension, when the patient lay prone for an hour while the stomach was emptying itself. The diverticulum seemed to belong to the stomach but was not found at the laparotomy. The necropsy disclosed it extending up back of the pancreas. Goldammer has recently published a similar case. De Quervain and others have explained such findings as a functional spastic diverticulum production in the stomach, but Akerlund is convinced that the diverticulum in such cases is an organic formation but originating, not in the stomach, but at the duodenojejunal flexure. The roentgen shadow seems to locate it in the stomach, but this is only a mistaken interpretation of the roentgenogram. Akerlund's case and Goldammer's case were identical apparently with de Quervain's and Schlesinger's four cases and, as in them, the diverticulum could not be found at the laparotomy.

*Polydactylous Families in Norway, K. Bonnevie.—p. 601.

*Vagus Neuroses after Influenza, F. Gundersen.—p. 673.

*Influenza Epitonia, I. Sævi.—p. 640.

*Proposed Isolation on Entericosis, N. Heintzen.—p. 643.

Polydactylous Families. Bonnevie has found in a certain district in Norway a number of families with a super-ordinary little finger, perfect or rudimentary, on the right hand and sometimes on both hands. Four or five generations of the different families are known to present these finger

anomalies more or less frequently. Inter-marriage between the different families shows that all of them trace back to one common ancestor, about 1600, who presented the finger anomaly in a pronounced form. Forty of his descendants in the six different families are known to have been polydactylous, and not all the members of the families were examined. The polydactylism is shown in these families to be a primary dominant character, although checked in its development in some. There is no evidence of a weakening of the anomaly through succeeding generations. Examination of two apparently normal members transmitting the anomaly to their children, revealed a rudimentary knob at the base of the little finger. The University of Christiania has founded an Institute for Research on Heredity, and this is its first official communication.

Vagus Neuroses After Influenza.—Gundersen remarks that the clinical picture of vagus affections has been built up on theoretical premises rather than on study of the patients themselves. He does not know of any published cases of functional vagus affections or vagus neurosis like the case he describes here in a medical student. After an apparently mild attack of influenza, he developed attacks daily, lasting an hour or less, and coming on suddenly with intense pain in the heart region. The pain spread to the left shoulder and he felt as if his heart stood still and then beat slowly and faintly. There was also pain in the stomach, and the left part of the epigastrium protruded until the close of the attack. The physician called at the first attack diagnosed hysteria. Similar attacks followed on succeeding days. The pulse dropped suddenly from 70 to 55, and vision seemed impaired, and there was difficulty in breathing, and polyuria followed the attack. The clinical picture thus included bradycardia and pain in the heart, local meteorism from intestinal spasm, spasm in the pharynx and bladder (polyuria), and eye phenomena probably from spasm in the ocular muscles. The young man was given bromids and atropin after these attacks had been returning daily for two weeks, and they subsided permanently. By exclusion, Gundersen diagnoses the case as allied to anaphylaxis, the vagus neurosis being a manifestation of auto-intoxication.

*Isolation Period for Scarlet Fever, V. Bie.—p. 1011.

Isolation Period for Scarlet Fever.—Bie remarks that authorities differ in regard to the length of time scarlet fever convalescents must be kept isolated. Some say to four, others up to eight weeks. He analyzes the experiences at the Blegdams-hospital where the isolation period has been gradually shortened more and more. No effect on the incidence of the disease in the town could be detected when the scarlet fever patients were discharged the thirty-eighth day. The large number of scarlet fever patients, 3,175, and the nearly three years' experience seem to justify acceptance of the conclusions that thirty-eight days is a long enough period of isolation. Sorensen with 10,299 patients in ten years and an isolation period of fifty-six days, had 3.6 per cent. return cases, while Bie had only 1.9 per cent. with his thirty-eight day period. Sorensen's percentage varied very little from year to year while Bie's percentage showed a constant downward trend, from 2.3 to 1 per cent. This testified that the shortening of the isolation period had not contributed to spread the disease; return cases and complicating nephritis were no more frequent, and it is possible that the period might be shortened to thirty-five days. He pays great attention to the nose and throat before discharging the patients, heeding this more than desquamation. One child was kept in the hospital for sixty-four days as the nasopharynx still showed pathologic conditions kept up by adenoids. When finally allowed to go home the sixty-fourth day, the child's sister became infected and was brought to the hospital the sixth day.

SUGGESTIONS FOR AN IDEAL COURSE IN THERAPEUTICS *

W. A. BASTEDO, M.D.

Assistant Professor of Clinical Medicine, Columbia University College
of Physicians and Surgeons
NEW YORK

My text I take from McCrudden: "The teaching of therapeutics is one of the weakest points in the training of the medical student." Ideal, as I employ it, does not mean visionary and unattainable perfection, but rather "that which is conceived as supremely excellent or very desirable." I shall consider the subject under three headings, namely, the pretherapeutic teaching, the theoretical therapeutic and the clinical therapeutic teaching.

I. PRETHERAPEUTIC TEACHING

To make any course successful it is requisite that both students and teachers shall have adequate preliminary training in the fundamentals on which the course is based. One of the criticisms often aimed at clinicians in the dispensary and hospital is that they teach many absurd things in treatment because they are familiar with neither physiology nor drug actions. In some measure this is true. But the ultimate remedy lies, not in abolishing the teaching of therapeutics by merely clinical men, but in increasing the time allotted in the curriculum to the pretherapeutic subjects, physiology, physiologic chemistry and pharmacology. Our present students, some of whom will in time become the teachers and leaders in medicine, must be more highly educated in methods of physiologic and pharmacologic thought, and must by the experimental method receive greater instruction in how to make observations, how to draw inferences and how to collate results. It goes without saying that the physiology and pharmacology teachers have a right to expect that the material of their teaching shall be utilized in the later years.

II. THEORETICAL THERAPEUTIC TEACHING

The purpose of theoretical therapeutic teaching is to orientate the student in the subject, that is, to familiarize him with the whole matter of it.

In this course it is necessary that the student should learn how to combat every symptom that may appear at every phase of every stage of each of the diseases of internal medicine. He does not study individual cases. But since only rarely in any patient do all the symptoms require treatment, it should be the effort of the teacher to impress this on the student by pointing

out the probable course of a patient's illness if this or that symptom remains untreated. In this course, furthermore, it is necessary to write prescriptions, but the teacher should discourage the student from attempting to memorize set prescriptions. Last, but not least, the student should be made to justify or condemn all therapeutic recommendations by physiologic and pharmacologic argument; and because of this the teachers are best chosen from among those clinical men who have had intensive training in pharmacology or experimental therapeutics.

All didactic lectures should be abolished except a very few that may deal with principles, such as those of dietetics, serum therapy, electrotherapy and other special therapies; and the teaching of each of these should be assigned to the department to which it naturally belongs, for example, the principles of serum and vaccine therapy to the departments of serology and bacteriology, and the principles of organotherapy to the department of pharmacology. It is not to be expected that the principles underlying these therapies can be adequately taught by a clinical therapist.

III. CLINICAL THERAPEUTIC TEACHING

A. The Type of Clinical Teacher.—In the best teaching in any subject it is a fundamental proposition that facts must be handled by the student at school as he may be expected to handle them in the world at large; or, to apply this idea in therapeutics, the undergraduate must be taught to handle the facts on which the treatment is based as he may be expected to handle them when he is practicing medicine. It follows from this that his clinical therapeutic teachers must be practicing physicians, men who will understand the needs of the sick patient in the home and the physician's office, and will take cognizance of all factors, from outside the patient as well as from inside him, that may influence the patient's mental and physical comfort. I am mindful of the words of Sir James Mackenzie in speaking of cardiac decompensation: "It may be taken as an axiom that if the patient does not get sufficient sleep he will never get well," and of those of Ray L. Willbur: "Reassurance is often as comforting as opium and has fewer after-effects." Indeed, a sick body is not infrequently only the physical expression of a sick mind. In many instances, the removal of an outside influence has an important scientific value as a measure of treatment, and has as pronounced a physiologic action as the most potent of pharmacopeial drugs. Better for our students we could not do than have them see at work those clinicians who appreciate the personal relations of the patient, and who not only inspire by their erudition and enthusiasm, but also show that humanity that always

* Chairman's address, read before the Section on Pharmacology and Therapeutics at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

leaves the patient, whether poor or rich, better in spirit because of the medical interview. Such men always remember that they are treating a patient that has a disease rather than a disease that has the patient.

B. Deciding on the Treatment.—Furthermore, students should be taught to practice as the great consultants practice. These, when outlining a plan of treatment, remove themselves from the patient and the patient's friends, to sit down quietly and review the data at their disposal in a clear, cold, logical manner, without sentiment, until the plan is matured. Then, in dealing with the patient, they show kindness and consideration.

In teaching the student in the dispensary or at the bedside, why expect him to give offhand the treatment of each individual symptom without consideration of the patient as a whole? Let us rather habituate him to getting away from the patient, in small clinic sections, perhaps, for that moment or two of thought which will permit a mental survey of all the probabilities in the particular case. For in our clinical work we are not treating tonsillitis, typhoid fever and gastric ulcer, each with its numerous possibilities in the way of symptoms, but we are treating a particular patient with tonsillitis, typhoid fever or gastric ulcer at the particular stage and with only such conditions or symptoms as that particular case manifests. If we teach a student to exact uninterrupted moments for consideration of the treatment, may we not save him later from the many therapeutic failures which result, at least in part, from a habit of permitting submergence of his thoughts on the patient's symptoms by an irrelevant introduction of the anxieties of friends, and sometimes the neighborhood gossip?

C. The Use of Specialists.—We are teaching students that they may become practitioners. Then, in order to teach the student in a practical manner, we must teach him to think and act as he should when he is a practitioner. Therefore, let us inquire into the method of the higher type of practicing physician. When he wants the very best for his patient, he does one of two things: either he calls on a specialist, or he adopts a plan of treatment that has been approved by specialists. Why does he call a specialist or accept as valuable only what the specialist approves? Because he looks on the specialist as one who, by concentrating his knowledge, his powers of investigation and his clinical cerebration on a particular class of patients, is able to diagnose and apply measures for relief in a more certain manner than can be done by others.

Perhaps the first group of men who separated from general medicine to practice a specialty were the surgeons. Then followed neurologists, gynecologists, and all the others that we have, until eventually, for sheer self-protection, the leaders in medicine who remained were forced to give themselves a name, and for want of a better, chose that of internists working in the field of internal medicine. But with the great advances in this field it soon became evident that no one man could give intensive attention to the whole of it; and as a consequence, in internal medicine itself, alone or sometimes joined with related subjects, there have come to be specialties, such as gastroenterology, cardiology, syphilology, tuberculosis, tropical diseases, contagious diseases, kidney diseases and the diseases of metabolism. We even have specialists in diabetes, in intubation, in transfusion and in hay-fever. As we have general surgeons and special surgeons, so we have

general internists and special internists. Is this specialism absurd? Not at all! Medicine has possibly lost something by specialism, but it has gained much more.

That eminent and inspiring teacher, Sir William Osler, said of specialists:

They have contributed largely to inculcate the idea of thoroughness. Better work is done all along the line, and a shallow diffuseness has given place to the clearness and definiteness which comes from accurate study in a limited field. The day has gone by for Admirable Crichtons, and although we have a few notable illustrations in our ranks, of men who have become distinguished authorities in several fields, such are necessarily rare and likely to become still more uncommon.

This he said twenty-five years ago. Think of the strides in specialism that have been made since that time! Further, Dr. Osler says:

The public has not been slow to recognize the advantage of a division of labor in the field of medicine. It must, indeed, be a comfort to thousands to feel that in the serious emergencies of life expert skill is now so freely available.

In any subject in medicine, for the latest and most approved methods, whom do we ask? Is it the general practitioner? Or, in internal medicine, is it the general internist? For answer we need only refer to the program of this section, on which we see papers scheduled from eminent specialists, two in transfusion, two in alcoholism, two in the realm of anaphylactic or related phenomena, one in diabetes and one in the field of radium therapy. We asked these men to address us because they are specialists and therefore authorities in the subjects on which they are to speak. I would not have you think for a moment that any one of these men knows nothing beyond his specialty. On the contrary, these and all worthy of confidence in a specialty are men who, while knowing everything about one thing in medicine, know also something about every other thing in medicine. Did it ever strike you that one of the grandest features about specialists is that they are all preeminently therapeutists, their whole aim in laboratory, hospital, dispensary and private practice being to attain therapeutic results?

If, then, we grant that the greatest heights in diagnostic skill and successful treatment are reached by specialists, and that they are the men who can give the best to the general practitioner, let us by all means utilize them to give the best to the student.

To this I give emphasis because, in spite of its appreciation and utilization by the profession at large and by the public, specialism inside the realm of internal medicine has failed to find encouragement in some of the more conservative, or perhaps I might say more antique, colleges and hospitals. In internal medicine we are almost at the dawn of specialism, and I am sure that nobody here thinks that that trend is going to stop where it is.

D. Dispensary and Hospital Services.—Even hospital training leaves the graduate therapeutically unfit; and this may be accounted for, without reproach to the attending physicians, by the fact that today the hospital services are as large as they were when internal medicine was a much smaller subject. So that by the time the attending physician has ended his discussion of the complex and intellectually stimulating problems of diagnosis, he lacks the time to do more than outline the treatment in a brief and routine fashion, and frequently leaves it entirely to the youth-

ful house physician. Here, I myself can cast no stones. Because of this tendency we see every day in our best hospitals cardiac patients given caffeine all day to the verge of poisoning and, as a consequence, failing to get necessary sleep until deluged with dangerous doses of morphin; nephritics with edema nauseated by large daily doses of salts to remove liquid, but not having liquid stools; patients with chronic constipation left to the chance shots of a sapient junior who makes evening rounds; and diabetics receiving diets in which all or most of the daily allowance of carbohydrate is given at only one of the meals, so that sugar unnecessarily continues in the twenty-four-hour urine. And the most astounding fact of all is that often the attending physician passes these things unnoticed. And interns with this training, and students so trained, we are turning out to practice medicine.

By a proper division of labor in the hospital and dispensary, and by having an adequate force, which should be made up partly of specialists, each man in his own sphere can be assigned that amount of work which will permit him to give *equal attention to both diagnosis and treatment*. In other words, the rounds in the hospital must be just as much therapeutic as diagnostic. Not only will this result in gain for the attending physicians, the interns and the students, but it will prove a very great boon indeed to the now only too frequently mistreated patient. Moreover, it will permit a proper collation of the results of treatment, a matter on which I lay great stress. With proper assistance, it should be the duty of every attending physician to summarize on every record, each week or on the patient's discharge, the therapeutic measures employed and the results obtained. In course of time this will furnish many data relative to the successes and failures of like treatment in many cases with like conditions, and to the comparative values of different methods of treatment, including, in some instances, the method of watchful waiting.

It would seem that even now, as the result of laboratory and clinical research, every therapeutic recommendation might properly be required to meet the challenge of the experimental test; or if it cannot, must be accepted only tentatively and transixed with a question mark.

E. Classes of Teachers.—I am well aware that there are two seemingly irreconcilable ideas regarding the teaching of therapeutics, namely: Shall therapeutics be taught by the clinicians in each branch of internal medicine, or, since at the present time we must still employ drugs extensively, shall it be taught by those who have given such intensive attention to the action of drugs that they can think physiologically and pharmacologically? At present both classes of teachers must be used. In the future, whether near or distant, I trust that all advanced medical men will think physiologically and pharmacologically.

F. Demonstrations in Special Therapies.—Instruction should be arranged for in the use of other remedial measures besides drugs and psychotherapy. In certain of the special therapies, demonstrations should be given in the dispensary or hospital best equipped for the purpose, and I wish that all hospitals might be so equipped. For example, electrotherapy might be taught in the neurologic clinic or hospital ward, mechanotherapy in the orthopedic clinic or in a hospital with a Zander

equipment, and massage in the clinics of medicine, surgery and orthopedic surgery.

G. Need for Large Clinical Institutions.—I might further suggest that for concentrated teaching in medicine we need large clinical institutions so that the patients of each kind will be sufficiently numerous to permit a proper grouping and consequent satisfactory division of labor. This completes my suggestions.

PRESENT NEED AND TENDENCY

A physician's ability to treat his patients successfully is what constitutes his direct personal value to them, and it is the ultimate *raison d'être* of his calling. Granting, then, the truth of our text that today "the teaching of therapeutics is one of the weakest points in the training of the medical student" this is my ideal: *In the college curriculum and in the hospital have treatment given the consideration that it demands in the practice of medicine*, and have it taught both by special students of therapeutics and by those who would be considered by the medical world authorities in the sundry groups of diseases.

To install improvements or to change a plan, no time could be more propitious than the present, for already eight states, before giving a license to practice medicine, demand a year of internship in an approved hospital; and eight medical schools have increased their course of study to five years. Other states and other schools must soon follow. Hence, in the resulting enlargement of the curriculum and the increased standards of practice, may we not hope that these ideals may be reached?

SUMMARY

My suggestions for an ideal course in therapeutics are:

1. In the pretherapeutic teaching, insure habits of physiologic and pharmacologic thought by allowing more time in the college curriculum for training in physiology, physiologic chemistry and pharmacology.

2. For the theoretical teaching, orientate the student in the subject by systematic quiz-lectures covering all the diseases of internal medicine in all their phases. Select the teachers for this from among those practicing physicians who, through intensive work in pharmacology or experimental therapeutics, have acquired special ability and special knowledge for thinking physiologically and pharmacologically. Omit didactic lectures, except the few required to teach principles in special fields of therapy, and assign these to the departments best fitted to give them.

3. For the clinical teaching: (a) Teach the student to review the patient as a whole rather than as a collection of isolated symptoms, and teach him to isolate himself while he deduces the treatment from the available data.

- (b) In the dispensary and hospital, utilize specialists in the sundry branches of internal medicine.

- (c) In the hospital, increase the medical staff and, as a consequence, reduce the size of the service assigned to each attending physician. Demand that rounds be therapeutic as well as diagnostic, and that the results of all therapeutic measures be recorded.

- (d) Have special clinics and ward teaching devoted to treatment by clinicians who are versed in the actions of drugs and are willing to devote special attention to the problems of therapeutics.

(e) For teaching in the special methods of therapy, arrange for demonstrations at those dispensaries and institutions in which the necessary operator and equipment are available.

(f) In the dispensary and hospital have the patients grouped to permit of a satisfactory division of labor.

(g) Above all things, teach the student to think as the practicing physician should think.

57 West Fifty-Eighth Street.

EFFECT OF THE WAR ON MEDICAL EDUCATION *

HORACE D. ARNOLD, M.D.

BOSTON

The emergency of the great war put us all, as a nation and as individuals, to an unusual test of efficiency. Much of value may be learned by the study of this experience. It is not only desirable that the knowledge thus gained should be utilized for the benefit of the community, but it is our duty to the soldiers who won this war—especially to those who made the supreme sacrifice—to make the most of this unusual opportunity and to secure for the people of the nation benefits which will in part offset the devastation of war.

This duty to learn lessons of value from our experience in the war applies to all branches of human endeavor. We are asking what we may learn that will improve medical education. We have properly taken pride in the great advances in medical education in the past fifteen years—but many of us were too well satisfied. Of course, we knew we had not reached our ideal, but I think few of us realized how far the average medical school is from that ideal.

"By their fruits ye shall know them." Approximately one third of the physically fit registered physicians of this country were actually submitted, in army service, to a searching practical test of efficiency. Never before was there such an opportunity to test the product of our educational institutions in medicine. We have in this country a few of the best medical schools in the world, yet not one but can learn much of value from the deficiencies of some of its graduates under this "acid test." The general verdict in regard to the average graduate from what have been regarded as good medical schools is disconcerting to earnest medical educators. The need for further improvement is greater than we thought. It is probable that this lesson, learned from the war, will give added impetus to our endeavors to improve medical education.

Already these matters are receiving attention. It is too early to formulate final conclusions. Statistical data are not yet available for this study. Yet perhaps some of the most valuable lessons will be learned from the general observations and impressions of intelligent medical teachers who have been in a position to observe the qualifications of considerable numbers of medical officers. My contribution on this subject is based in part on personal experience and in part on the observation of others. It is not intended to be an exhaustive or complete study of the subject—rather is it an opportunity to record some personal impressions and conclusions, while the events are still fresh in mind. It has been my aim to avoid dogmatism and to

check my personal opinions, as far as possible, by the experience of others who had better opportunities for observation in active field service.

DISORGANIZATION OF MEDICAL EDUCATION

The immediate, obvious effect while the war lasted was the serious disorganization of medical education. The chief factor was the loss of the teachers who volunteered for military service. This, however, was a temporary effect, which will soon be recovered from as these men return to civilian life and duties. It is believed that they will bring to their teaching a stronger feeling of service, a greater earnestness of purpose, and a broader knowledge of the application of medical science, which will make them more valuable teachers.

The removal of so many of our best teachers had an undesirable effect on the quality of the instruction given in many cases. This, of course, has varied in different places. How serious this injury may be, and how much it will affect the thoroughness of the training of those who were studying medicine during the war, cannot be estimated at the present time. This is a problem that demands serious consideration on the part of medical schools that suffered in this way; and the defects can be offset, to some extent at least, before these students graduate. On the whole, the ideals and standards of medical education were maintained unimpaired during the war, and it is not believed that these standards will be lowered in any way as a result of this experience. Rather has the need of maintaining high standards been emphasized.

The effect of such impairment of the quality of the instruction was lessened because of the greater earnestness and better application on the part of the students. This was due, in the case of the better students, to the spirit of earnest enthusiasm so commonly engendered by the war, which caused the individual to put his very best effort into whatever he was doing. These students were "doing their bit" in the way that was considered wisest. But under the draft regulations and the resulting army supervision of medical education, the dull, lazy or indifferent student found a special incentive for work in the knowledge that failure to keep pace with the progress of his class meant active service as a private in the ranks. More than one dean has expressed the wish that some similar incentive to work might be a permanent feature in education.

BENEFITS FROM ARMY CONTROL

The enforcement of the regulations of the Surgeon-General, in carrying out the selective service regulations, was not only useful in maintaining the accepted standards of medical education, but resulted in the discontinuance of a few of the poorest schools. The privileges extended to medical students by the selective service regulations were limited to students in "well-recognized" schools—and the standard adopted for a "well-recognized" medical school was recognition by the state boards of medical examiners in 50 per cent. of the states. This lenient, though fair standard practically excluded the schools in Class C of the classification of the American Medical Association. So large a proportion of the students in these schools were taken by the draft that several of these schools found it impracticable to continue.

In another way the army control was useful: in securing a stricter enforcement of regulations, especially those concerned with the admission and promo-

*Owing to the lack of space, portions of this article have been omitted. The complete article appears in the author's reprints.

tion of students, and greater uniformity in the regulations governing these matters. Laxity in this respect was not usually intentional on the part of the school authorities. It was most commonly due to carelessness on the part of assistants; but sometimes it was due to the indifference of those responsible for the administration of such regulations, or to the persistence of a leniency in interpretation that was more common a few years ago than it is now. As a result of this army supervision the authorities of the medical schools in general have, I think, a keener appreciation of their responsibilities for the enforcement of such regulations; and care in these matters will continue and medical education will be improved in consequence.

DEFICIENCIES IN MEDICAL TRAINING

Chiefly as a result of the stimulation and wise guidance of the American Medical Association, through its Council on Medical Education, great improvements in medical education have been brought about in the past fifteen years. Looking back at the conditions that existed before 1904, we may well feel proud of the advance that has been made. But there is a danger that such feeling of pride in what has been accomplished may develop into a feeling of unwarranted satisfaction, and that we lag in the arduous journey toward the attainment of a really satisfactory condition of medical education. Looking behind to see how far we have traveled is not always the safest or best way of estimating how far we still are from our journey's end, especially when we journey toward a goal that still advances during the time that we are traveling.

It was to be expected that many of the older graduates, who received their training before these advances were generally adopted, would make an unsatisfactory showing in the efforts of the Medical Department to carry to the fighting men the benefits of modern scientific medicine. But deficiencies in training were not confined to these older men—or to the graduates of poor schools. The proportion of younger men—of those who graduated within the past decade—was very large, and the experience of the Army is a reasonable test of the results of modern medical education.

Experience as chairman of an examining board for the Medical Reserve Corps enables me to say that the poor medical schools do not turn out safe practitioners for the community, even though they succeed in passing the state boards. My service as an examiner for the Medical Reserve Corps extended over a year and a half, from the time of the mobilization for the Mexican border, in the late spring of 1916, until I was ordered to the Surgeon-General's Office toward the end of November, 1917.

Definite instructions that candidates from low grade medical schools should not be examined for the Reserve Corps were not issued by the Surgeon-General until about the first of September, 1917, and up to that time candidates who were graduates from such schools were examined by our board. With very few exceptions, candidates who graduated from Class C medical schools failed to pass the examinations successfully. It has been asserted by one of the local Class C schools that the Boston examining board was prejudiced against the graduates of that school, because the members of the board were graduates of the Harvard Medical School. Such a claim is unjustified, is practically absurd, because the members were among the leading physicians of Boston, and no explanation of the attitude of the board is called for

because of any such charge. But such an explanation is important in estimating the value of our study of the product of poor medical schools. What I have to say applies to all Class C schools more or less, the degree varying in direct proportion to the poorness of the school.

The function of the examining board was to select those candidates who were qualified physically, morally and professionally to care properly for our soldiers. We were acting for the Army only, and it was definitely understood by all members of the board that the selection of physicians for military duty was to be based on a fair judgment of the evidence of qualifications for such duty, and was not to be influenced by any preconceived ideas on the subject of medical education or otherwise. It was fully recognized that some men of ability might for some reason have attended a poor medical school, and might especially through subsequent study or experience, have overcome this handicap and become qualified for the duties in question. The need for medical officers was sufficiently great to demand the acceptance of all properly qualified candidates.

If a man was found to be qualified physically and morally, the next step was to ascertain his professional attainments by an oral examination. If this was not satisfactory, he was given a further chance in a written examination. The oral examination was under the control of the board, but the written examination was set by the Medical Department of the Army, the sealed papers being opened only at the time of examination, and in the presence of the candidates. While the papers in the written examination were marked by members of the board, they were sent to the Surgeon-General's Office for review, and for independent marking if desirable. The system was practical and fair, both in conception and execution.

The patriotic desire to serve in the war was not limited to the graduates of good schools, and it was the aim of the examining board to give the patriotic graduates of poor schools—as long as they were permitted to examine them—a square deal and an absolutely fair chance to demonstrate proper professional qualifications. Some of these men had ability more than sufficient to become excellent physicians, had they had an adequate training, and the members of the board were greatly impressed with the injustice, both to these men and to the community, by the poor schools which offer an inadequate training when a satisfactory training can be obtained in better schools at no greater expense.

It may be said in general that the brighter graduates from Class C schools showed a fair knowledge of matters that could be learned from textbooks and quizzes. They were decidedly deficient in practical knowledge of disease, such as would be gained from good laboratory and bed-side teaching. They were particularly deficient in any practical knowledge of contagious diseases and other infections—matters of extreme importance not only in the camp life of the Army, but in the ordinary life of the community.

Two of my stock subjects, in the oral examination of such candidates in medicine, were the means of early detection of typhoid fever and of tuberculosis. I think every one will admit the importance of the recognition of each of these diseases in an early stage, both for the proper care of the individual and to prevent the spread of these diseases through the com-

minity or the camp. Yet hardly a graduate from a Class C school was found who, without further instruction obtained elsewhere, was qualified for such work. Physicians so poorly qualified are a menace to the public, for they assume the responsibility of protecting the public from the danger of the spread of such diseases.

WHY SUCH SCHOOLS SHOULD CEASE TO EXIST

Actual experience with medical officers in the field and in camp showed that the Army standards were not too high, but rather raised the question whether the standards, or their administration, were not dangerously low. If these requirements are essential for the proper care of soldiers, are they not equally essential for the proper care of the public in time of peace? It seems to me that it is high time for the medical profession to say even more boldly and emphatically to the public that low standard medical schools and careless or indifferent licensing boards in medicine are a menace to the health of the community. There is no longer a reasonable excuse for the existence in this country of a medical school so poor as to be placed in Class C by the Council on Medical Education. After all the educational work on this subject by the Council, and patient waiting for improvement, a school that remains in this class must have in control men who cannot, or who will not, raise the standard of the school to a proper level. Such schools should cease to exist. If they continue, they should not be recognized by state licensing boards in medicine. Yet by the last reports some of these schools were recognized by from a third to nearly half of the licensing boards.

NEED FOR IMPROVEMENT IN METHODS OF LICENSURE

I know very well that in some instances the licensing boards in medicine recognize Class C schools because they have no legal authority to discriminate in their recognition of medical schools. These boards should endeavor to get such legal authority from the legislature. The experience of the Army in finding so many licensed practitioners of medicine professionally unfit for the medical care of our soldiers should be a strong argument for improvement in the methods of licensure. Improvement in this respect implies, first, authority to insist on an adequate medical training before a candidate is accepted for examination; and, secondly, a sufficiently thorough examination to test his efficiency.

In some cases it may be necessary to educate public opinion before such authority can be obtained. The opportunity for such education of the public is better today than ever before, for the war has given the millions of men in service a better insight into the value of a good doctor; the experience of the community in putting up with the scarcity of physicians—including those who were not qualified to take care of the soldiers—has given those who stayed at home a better insight into this problem. The medical profession will be derelict in its duty if it does not take advantage of this state of public opinion, and endeavor to secure better laws governing the licensure of physicians, and better enforcement of the laws that already exist.

This campaign for the education of the public should be pushed not for the benefit of the medical schools or of the profession, but for the protection

of the public itself—until a license to practice medicine is based on a satisfactory general education, a sufficient knowledge and practical training in the sciences on which medicine is based, and a proper theoretical and practical training in the fundamental medical sciences and in the clinical branches of medicine. Only after such thorough training is a physician qualified to recognize and correctly diagnose disease when it exists. Only with such training can he bring to the public the advantage of modern scientific medicine. If he has this foundation and is skilled in diagnosis, the question of the method of treatment may be left safely to his judgment. These requirements should be uniform for all candidates for licensure, whatever the method of care of the sick is to be; for the practice of any branch or form of medicine implies the ability to recognize conditions of disease.

Theoretically, if a man has the qualifications mentioned above, it matters little where or how he obtained his training. Practically such a training can today be obtained only in a good medical school and on the basis of the premedical education required by the better schools. A satisfactory test cannot be based alone on the best examination now given by any state board. Hence the importance of insisting that a candidate for licensure shall have had an adequate preliminary education and have completed his medical course in a really good medical school. This problem of the requirements before examination for licensure should not be permitted to be confused by any questions of schools of medical treatment, or sects or cults in medicine. And on this point also the public needs to be enlightened.

BASIS OF JUDGMENT OF SCHOOLS

Judgment of medical schools, irrespective of sect, should be based on actual performance, on the completeness and thoroughness of instruction, and on adequate equipment. It should not be based on the paper requirements of catalogues, which are too often a camouflage to cover inadequate training. Tabulations of subjects and hours—the common arguments of sectarian schools for equal recognition with regular medical schools—have no real value unless backed by laboratory and clinical advantages and quality of instruction equal to those of good medical schools. The same method of inspection that is applied to the regular medical schools has shown the schools of the so-called medical cults to be lacking in these essential respects, as far as such inspections have been permitted.

I have stated that Class C schools should not be recognized by state licensing boards in medicine. If the public were awake to their own interests, Class B schools and a number of schools at present ranked in Class A would also not be recognized. This statement is warranted not merely from a theoretical educational standpoint, but by the practical experience of the Army in this war. But there is danger in raising standards for licensure so rapidly as to get too far ahead of public opinion. It is a question how far such standards should be advanced as long as the public is so tolerant of medical cults as to allow their graduates privileges in practice which should be granted only to those who are thoroughly trained in the investigation and recognition of disease.

It is expected that the Council on Medical Education will soon make a new survey and classification of medical schools. The leniency in grading, wisely

exercised at the last classification, is not warranted now; and, if such classification is to mean much from an educational standpoint, a number of schools now ranked in Class A cannot be retained in the highest class designated by the Council. This question is complicated by the consideration that the Council has looked on Class A as a standard for acceptable schools, not only from an educational point of view, but also from the point of view of recognition by state licensing boards. As matters stand today, the practicable standard for recognition must be placed considerably lower than is desirable from the educational point of view. The lower limit for Class A schools should be raised somewhat higher than it is at present; but because Class A is the accepted standard for licensure in a number of states, it is not practicable to raise the limit to the level demanded by educational considerations alone. It would seem desirable to establish in some way a higher subclass, to include only those schools which are found to be *fully* satisfactory from an educational standpoint.

Army experience would seem to indicate that, in the rating of medical schools, greater emphasis should be placed on the thoroughness of the instruction in the fundamental medical sciences, on the methods by which the student is trained actually to apply this scientific knowledge to clinical cases, and especially on the extent and excellence of the teaching of clinical subjects to individual students. The textbook, the recitation, the didactic lecture, and the clinical lecture before a whole class still have their places in medical teaching; and valuable time would be wasted if *all* instruction had to be repeated over and over again to small sections. But a satisfactory clinical training can be obtained only in such small groups that the student can handle the patients himself, and can receive individual attention from a well-qualified teacher. Too many of our students in reputable schools have received most of their "clinical" training from amphitheater seats; they have had only written examinations to test their qualifications for practice; and, if they have taken an intern year, it has helped them little because the average hospital is poorly equipped and the staff too busy or too indifferent to instruct the intern, or not qualified to teach modern medicine. It is no wonder that these men in the army hospitals could not make a dependable physical examination of patients. The clinical teacher, with experience as medical chief of an army hospital, who in my hearing has expressed the greatest tolerance of such men, said: "After all they were no worse than the average practitioner in civilian life." I think he is right. But what a comment on the average training given in an average medical school!

VALUE OF INTENSIVE CLINICAL TRAINING

The Army has taught us another valuable lesson: that great improvement in such men can be secured by intensive practical clinical courses under competent instructors. Medical schools will render an immense service to the community if they will make adequate provision for similar training of practitioners. Adequate training means much more than the ordinary "postgraduate" course given in the past. Here is a definite need—of so great importance to the community that provision for such training might well be developed by state authorities. It is as legitimate public welfare work as the measures for preventing disease now being so widely adopted by public authorities.

CONCLUSION

Such are a few of the reflections that occur to me in considering what the effect of the war will be on medical education. The need of further improvement is clear. In some instances, the direction for such improvement is clearly pointed out. In others, careful study and deliberation will be necessary. I feel sure that medical educators will give these matters serious attention, and that the improvement of medical education will receive a great impetus as a result of our war experience.

THE FIFTH, OR INTERN, YEAR

• JOHN MILTON DODSON, M.D.

CHICAGO

The fifth, or intern, year as a requirement for graduation in medicine has been in operation for a year in at least two institutions: the University of Minnesota Medical School and Rush Medical College. The methods of administration adopted in these schools are essentially the same, although they were arrived at quite independently. In each school the matter has been placed in the hands of a standing committee of the faculty. This committee determines what hospitals are to be approved, and posts or prints the list for the information of the students who are seeking internships. These lists are as yet provisional and tentative, and a student who contemplates accepting a service in a hospital not on this list reports the fact to the committee, which then investigates the hospital and decides on its acceptability.

REGULATIONS GOVERNING THE INTERN YEAR

Of the methods of procedure at Minnesota, Dr. Litzenberg, the chairman of the Committee on the Intern (called there the seventh) Year, writes:

On account of the war, the seventh year requirement was waived last year for all men who entered the service. Others were required to take the seventh year in hospitals under our supervision. The exact number I cannot say. However, this year the whole class were required to take the seventh year. We had no difficulty in securing good appointments for all of the men.

We have no printed rules and regulations which we can give you, but our requirements are about as follows: Each student is required to take his seventh or intern year in a hospital approved by the Seventh Year Committee. This requirement conforms in the main to the rules laid down for a Class A hospital by the American College of Surgeons. This must be of sufficient size, must have a well conducted clinical laboratory, roentgen-ray department, and an organized staff of high class men. Each student is required to register with the registrar of the university for his seventh year, giving the name of the hospital in which he is to serve his time. We will not let our students go to hospitals unless they will agree to furnish them high class clinical instruction, and we ask the superintendent of the hospital to oversee the instruction which the interns are to get or to nominate some member of the staff who will be responsible for the teaching of the interns. It is our desire to arrange systematic teaching for the interns and not the hit or miss "knowledge by experience" plan.

We require that the student is to do his work in such a manner that he may be recommended for his degree after he has spent the seventh year in the hospital. Our requirements are explained to the superintendent of the hospital in cases where the hospital is not here, so that they understand our requirements. The interns are given distinctly to understand that this is an additional student year, and that the kind of

work they do will determine whether or not they will receive their M.D. degree. In Minneapolis and St. Paul, members of our own teaching staff supervise the work of the interns. It is their duty to see that the intern does his work well and that the staff give him proper instruction.

We feel that this additional year is necessary for the proper preparation of men to begin the practice of medicine, but we also feel that we have only made a beginning and that the work must be carefully planned and organized. If interns are to serve only in the same manner as in the past, there is no advantage in the additional year; but, under the proper supervision, we are convinced that it can develop as one of the greatest advances in medical education in recent years. On account of the interference of the war, this is the first year that it could be given a fair test. We anticipate that it will prove our contention—that a properly conducted clinical year in a well managed hospital, under systematic instruction, will greatly add to the quality of men turned out to practice.

The method pursued in Rush Medical College is quite similar, and printed regulations are given to each student. The work of the fifth year may be completed by an internship in an approved hospital or by a year of advanced clinical work in one of the departments of the college. On the satisfactory completion of the year's work, the student is entitled to his degree of Doctor in Medicine.

The student who elects an internship must secure a position in a hospital either by examination or appointment and immediately notify the dean, who will inform him promptly whether or not the hospital chosen is approved. During his service, the intern is required to report to some member of the faculty to whom he is assigned, and to submit copies of some of the case histories written by him. Whenever possible, the supervisor will be a member of the medical staff of the college in which the student is taking his intern service. If a student abandons an internship without the consent of the hospital authorities or without valid and ample reason, he will be denied his degree. An examination may be required at the end of the intern service. Unless excused by the faculty, the student must be present at the convocation when his degree is to be conferred.

The supervision of internships is under a committee on the fifth year assisted by such members of the faculty as they may designate. Each supervisor, so far as possible, shall visit and inspect the hospitals in which the interns under his charge are serving. He shall see to it that reports of the work done and case histories written by each intern shall be submitted as often as is deemed necessary. At the end of each intern service the supervisor will obtain from the hospital a report as to whether or not the intern has done satisfactory work. He will then make his report to the committee on the fifth year, stating whether each student under his charge is entitled to receive his degree with or without examination.

The committee assigns to each member of the class a "faculty supervisor" to keep in touch with the students during their year of hospital service, to advise and assist them and to report to the faculty, through the fifth year committee, when the service of each intern has terminated, his recommendation as to whether or not his work has been satisfactorily performed, and his eligibility for the degree. About 75 per cent of the interns last year were under the immediate supervision of the members of the faculty who were members of the medical staffs of the hospitals in which they were serving.

Fortunately, it has been possible in many hospitals to enlist the services of Rush graduates who are familiar with the ideals of standards of the institution, and who are glad to assist in this new movement. At intervals the resident supervisor sends to the faculty supervisor one or more clinical histories taken at random from those written by the intern. These are reviewed and later returned to the hospital. Each intern is encouraged to undertake, in addition to his routine duty, some piece of investigative work, the results including a survey of the literature on that topic, to be embodied in a thesis.

REPORTS OF INTERNS ABOUT HOSPITALS

For several years, graduates of Rush serving internships in hospitals outside of Chicago have been asked at the close of their term of service to send to the college a detailed statement in reference to the hospital in which they have served, with critical comments. In this way much information has been gathered of great service to the students of later years in deciding on the hospitals in which they would accept service. Such evidence, in reference to the character of a hospital and of the professional character and ability of the staff, needs to be carefully scrutinized, for once in a while, the report from a student will give evidence of personal animus against some member or members of the hospital. Such exceptions have been rare. On the other hand, from no other source is it possible to procure such direct, accurate and unbiased information concerning the character of a hospital, especially as to the personnel of the staff, altogether the most important item both from the standpoint of the education of the intern and of service to the patients. These interns, after a year of service in the institution, are in position to know about it. They are mature men, averaging about 27 years of age at the time of entering on hospital service, and their judgment is very much worth while. I apprehend that in any comprehensive survey of the hospitals of the United States, such as is being planned by the American Hospital Conference, recently organized, no information will be found of more value than that furnished by those who have served as interns within their walls. Some of the faculty supervisors have sought this information by formal questionnaires sent to the interns under their charge; others have simply asked the intern for a description of the hospital conditions, to be expressed in his own way. It remains to be seen which is the more effective plan.

THE INTERN YEAR—A UNIVERSAL REQUIREMENT

No graduate should enter on independent practice without at least a year of experience at the bedside under skilled and careful supervision. The experience of the medical corps of the United States Army in the world war strongly emphasized this need. In former times this practical training was obtained at the hands of a preceptor. This preceptor plan, never so well carried out in this country as in Great Britain, began to fall into disuse when the fundamental medical branches, physiology, bacteriology, etc., began to advance so rapidly and the annual session in the medical school was lengthened to six, seven, and soon to eight or nine months. The rapid changes in the methods of general practice, moreover, soon made it difficult for a physician to give much formal instruction or technical training to his student. For twenty years

or more the preceptor system in the United States has been practically obsolete.

For the great mass of students, the hospital internship is today, as it has been for many years, the only means of securing such training. Such hospital service has always been sought and secured by a few—usually the more ambitious and capable students. Until a comparatively recent time, however, such positions were so few and the graduates so many, that it is probable that 80 or 90 per cent. of the physicians now in this country began the practice of medicine, by themselves, immediately after graduating from the medical school.

INTERNSHIPS NOW EXCEED THE NUMBER OF INTERNS

During the last fifteen years there has been a remarkable increase in the number of hospitals, while the number of graduates has lessened. At the present time there is an annual demand for over 3,500 interns, while the number of graduates from the medical schools of the United States is less than 2,700 each year. For nearly a decade it has been possible for every graduate of a first class medical college to secure an internship, and from 90 to 95 per cent. of graduates of the best medical schools have done so. In five states, a year of hospital internship is now a prerequisite for licensure. Three other states will soon exact the same requirement, and other states are quite certain to follow their example. Eight medical colleges now require the intern year for graduation, and others are soon to do so.

The hospital internship is no longer for the privileged few, but will soon be required of every graduate in medicine. The real question now is, How shall this year of hospital service be controlled and administered? Shall it be left in charge of the hospitals; shall it be controlled by the licensing boards, or shall it be made an integral part of the medical curriculum by withholding the degree until its satisfactory completion, the faculty of the medical school being thus made responsible for its proper and efficient conduct? There seems to me to be no question that the last plan is the most advantageous for all interests concerned: for the students, the medical school, the hospital and the people whom these graduates are to serve as physicians.

It has been objected that most of the hospitals into which the graduates enter for intern service are not under the control of the medical college, and the faculty cannot, therefore, supervise the hospital work of its students in such a way as to insure its being worthy of credit on the course required for the degree.

The experience of the University of Minnesota and of Rush Medical College during the past year controverts that objection. But this very objection is one of the most forceful arguments for the general adoption of the plan.

THE MEDICAL SCHOOL AS A FACTOR IN THE IMPROVEMENT OF HOSPITALS

There is no greater desideratum in medicine in this country today than the general elevation of the standards of practice, both scientific and ethical, in hospitals.

In the important movement which has been initiated by the creation of the American Hospital Conference to survey hospitals of the United States and to encourage and assist them to improve their standards and methods of practice, no single factor is in position

to be so helpful or to exercise more effective pressure than are the stronger medical schools. The hospitals must have interns, the medical schools alone can furnish them, and they are in position to say to the hospitals: "Unless you can furnish to our students proper facilities and conditions for effective work under proper supervision and advice by competent, willing members of your medical staff, we shall not permit our students to enter your service. We shall be glad to assist you in every way possible to make your hospital work most effective as an educational process for your interns, and thereby it will most surely be made the best possible for the patients within its walls, and the most satisfactory for your medical staff and administrative officers.

"Proper facilities and equipment for thorough scientific work must be provided; exhaustive thorough examination be made of every patient; accurate, comprehensive histories be written, laboratory findings in connection with his own patients must be done, at least in part, by the intern under the supervision of a competent pathologist; the intern must not be burdened with so many hours of intern work that he has not ample time for study and reflection in connection with his cases; and, most important of all, there must be a responsible medical staff including some men who are capable of directing and advising the intern and who are willing to give the necessary time and effort to do this."

If all of the hospitals in which our students serve internships were as good as the best, it would perhaps be less important that the intern year be made part of the curriculum and be brought under the supervision of the faculty of the medical schools. It is because they differ so widely in efficiency, and that the kind of training which the intern receives varies so much, that effort should be made to improve the poorer institutions. No class of men are so well qualified to do this as are those who are engaged in medical education—the faculties of the medical schools.

FEW LEGAL DIFFICULTIES

Are there any legal difficulties in the way of making this intern year a requirement for graduation? Inquiry has been made of the medical examining boards in the several states in regard to this matter. In all but a few of the states, the student who has completed four years of work in a medical school may serve as an intern without a license to practice. In a few states he may take the examination for licensure without possession of a diploma. In Illinois and Wisconsin, special provision is made by statute, whereby the student presenting a certificate that he has completed four years of study in a recognized medical school may take the examination for licensure, and if he passes this, receive a temporary license authorizing him to practice as an intern only. This temporary license is replaced by a permanent license, without further examination or fee, when he has completed a year of internship and has secured his diploma from the medical school. In four states, South Carolina, South Dakota, New Jersey and Washington, no license can be secured without the presentation of a diploma, and one may not practice as an intern without a license. This restriction certainly should be repealed, otherwise the hospitals in these states will be unable to secure the service of interns from the medical schools requiring the intern year for graduation.

CONTINUOUS, SINGLE SERVICE THE BEST

Another rule which should be modified is that laid down in some of the states in which the intern year is a prerequisite for licensure, demanding that the intern's service shall be of the mixed or of the rotating type. The growing tendency in the best hospitals is in the direction of a continuous service for a year in one department. When this change was made in the Presbyterian Hospital of Chicago, some ten years ago, I realized that it was inevitable because long continuity of service is unquestionably in the best interest of the patient and contributes greatly to the comfort and efficiency of the attending staff. I felt, however, that it was an unfortunate change for the intern. I have changed my mind. After observing the results of the plan since the change was made, I am convinced that it is very much better for the intern to confine his work to one department for a full year, or at the very least for nine months, rather than to go hobnobbing from one service to another every few weeks. Only by remaining in one service long enough to become really efficient and well trained in that line does he secure the maximum pedagogic value from his hospital service. Of course, he ought, if possible, to follow a year of surgical service by six months or a year on the medical side; better still if the sequence is reversed, the medical work preceding the surgical. In hospitals when the number of patients is about equally divided between the medical, including pediatrics and neurologic cases, and the surgical cases including gynecology and the other surgical specialties, the ideal arrangement is for every intern to secure a year on the medical side, followed by a year in the surgical service.

LONGER HOSPITAL SERVICE FOR THE
BEST MEN

Does a two year service seem too long? Even that is not sufficient to develop strong, thoroughly trained men to whom we may look for leadership in medicine in the next generation. The reason this country has developed few great masters in the medical as well as in the other sciences is that we have been unwilling to devote ourselves to the long years of patient, grinding tutelage, advancing slowly, under recognized masters, until we have laid broad and firm foundations. I look to see the time when those interns who have proved themselves most capable and promising will advance after two years of internship to a second and then a first assistantship, and finally to the position of resident physician or surgeon or obstetrician—of course on a gradually increasing salary—remaining in the service of the hospital for a period of from five to seven or eight years. Men so trained, under a strong, capable medical staff, will be in a class all by themselves in the medical profession of this country. It is by such a procedure as this that the masters in medicine of the European countries have been developed, and that is why American physicians went to Europe in such large numbers, previous to the great war, for advanced training and post-graduate instruction. Moreover, it is only by some such plan as this that the rapidly increasing demand for interns can be met. The present wide discrepancy between the annual numbers of graduates in medicine and the vacancies in internships, would be much greater than it is were each intern to be assigned only so many patients as he can care for efficiently; and the excess of the demand over the supply is certain to become greater

in the next few years, for the hospitals in this country are multiplying rapidly, while the number of graduates in medicine is unlikely to increase at all for some years to come. If, therefore, this supply of available interns is to be no greater than it is now, the only solution seems to be a longer period of service from each one of those we have.

The response of the hospitals to the questionnaire as to their equipment, facilities, staff, etc., and to the request for cooperation in making the intern year of greater pedagogic value, has been very prompt and satisfactory. With few exceptions the hospital officials and members of the medical staffs seem quite as eager to improve the work of the hospital as are the college faculties to have them do so. The education of the intern is by no means the only function of the hospital, nor, indeed, its primary duty. Its first obligation is the care of the sick. As Dr. Warner¹ has pointed out, the modern hospital has come to be a complex institution with a number of purposes to fulfil. It must educate nurses, social service workers and hospital administrators. It ought, moreover, to provide for and to insist on research in clinical medicine. Fortunately, its many functions are not incompatible with one another, but are mutually helpful. Nothing is more certain to sustain and to advance the quality of its scientific work, and to conduce to the welfare of its patients, than is the participation by the staff in the education of its interns.

The extent of its equipment, and the number of salaries of full time or part time men on its staff, is limited by its financial resources; and very few hospitals are heavily endowed. The demands made on any hospital for improvement involving increased expenditure must be reasonable, for the sums available for such purpose are conditioned by the income of the hospital. The medical school can be helpful in advising hospital officials as to how they can best utilize the resources at their command. Few of our institutions are conducted more uneconomically and inefficiently than many of our hospitals. A hospital in which more than 50 per cent. of the annual income is expended for salaries of the administrative officers, and these are not few in number, is in need of services of an efficiency expert.

The cordial cooperation of the several national associations representing the interests involved in the present day hospital, through the medium of the American Hospital Conference, gives large promise of a nationwide improvement in hospital practice that will render the demand of the fifth, or intern, year as a condition of graduation much less difficult of administration. When this demand becomes universal and every student is assured of a year of clinical work as an intern, it ought to arrest the tendency (quite manifest of late, and very much to be deprecated) to force back into the sophomore year courses in clinical medicine, surgery and obstetrics. The sciences fundamental to medicine, anatomy, physiology, et al., are of such great and growing importance that the student should devote every working moment of the first two years exclusively to them.

Dementia Praecox.—The rate of incidence of dementia praecox is higher in large cities as a class than in small ones, but the individual exceptions to the rule seem to indicate that the size of the city is not the dominant factor.—*State Hospital Quarterly*, Utica, N. Y., May, 1919.

PLEA FOR A STANDARDIZED COURSE
OF INSTRUCTION*

THOMAS J. HARRIS, M.D. (NEW YORK)

Lieutenant Colonel, M. C. U. S. Army; Director, School of
Otolaryngology

CAMP GREENLEAF, FORT GILTHORPE, GA.

At the annual meeting of the American Laryngological, Rhinological and Otolological Society in 1912, the subject of medical education in its relation to the specialty of otolaryngology was one of the principal topics of discussion. It was the unanimous opinion that a reform was demanded, especially in graduate instruction, and a committee was appointed to consider the subject and present recommendations.

This committee, of which the chairman was Dr. D. J. Gibbs Wishart, presented a report the following year, which, among several recommendations, contained one to the effect that the other national societies covering this specialty be invited to appoint representatives to serve on a joint committee, whose business it should be further to consider the subject. The invitation was generally accepted, and a committee was appointed which held numerous meetings and three years ago presented the results of their deliberations in a report to the constituent societies. Considerable progress had been made toward the adoption of this report when the United States entered the war. This automatically stopped, for the time being, further action. It served, however, to supply the greatest object lesson possible for the vital necessity of this reform. This necessity, at an early period in the war, made itself apparent to those who had charge of this division of medical work in the Surgeon-General's Office. The result was the organization of the School of Otolaryngology at Camp Greenleaf, Georgia. This served to set forth in a way never before possible the true status of the specialty of otolaryngology in this country.

I desire, accordingly, to give briefly a history of the school and then to make certain observations based on our experience there.

ORGANIZATION

The School of Otolaryngology, Camp Greenleaf, was organized May 12, 1918, and the first class began its work on the eighteenth of the same month. On the first of these two dates, Lieut.-Col., then Major, Thomas J. Harris, M. C., reported under orders from the War Department as instructor in otolaryngology. A considerable number of student officers was awaiting instruction, and a class of sixteen was detailed to receive it.

It was part of a comprehensive scheme of post-graduate instruction for medical officers which owed its conception to the far-seeing mind of Gen. Edward L. Munson, M. C. The need of such training to render the medical man competent properly to do the work in the army which was to be required of him had already, before America entered the conflict, impressed itself on General Munson.

The full story of how it was put into execution at Fort Riley by Col. William Bispham, M. C.; at Fort Benjamin Harrison by Colonel Ashburn, M. C., and at Camp Greenleaf by Col. W. H. Page, M. C., of what has been accomplished by them, by their successors and by the officers working under them deserves to be,

and undoubtedly will be, reported in full at the proper time. It is sufficient at this time to say that the accomplishments proved to be among the most important, so far as medicine is concerned, brought about by the great war.

BUILDING

A room in Ward Q of the general hospital was set aside as a lecture room, and equipment sufficient to permit of beginning work the following week was gathered together. The school was operated in connection with the ear, nose and throat department of General Hospital No. 14, and soon outgrew the quarters assigned to it. This led to the removal of the school, in July of the same year, to McDonald Field, where two buildings and half of a third building were assigned for its use.

The lower floor of one of these (Ward 29) was set aside for clinical and teaching purposes. It contained two treatment rooms, 31 by 10 feet, with concrete floors and electric lights; a well lighted operating room, 24 by 21 feet, with a concrete floor; a sterilizing room; a private treatment room for officers; a dispensary room; an office for the director, and a lecture room, 48 by 24 feet in size. All of these were conveniently connected, one with the other.

The three wards, together, contained 128 beds, most of which were constantly occupied.

EQUIPMENT

At the beginning, the equipment of the department was exceedingly meager; one nasal speculum and a tongue depressor virtually represented all that the staff had to work with. A requisition for a complete list of instruments and equipment was sent in early, and in due time everything that was needed in an up-to-date ear, nose and throat clinic, both for treatment and for teaching, was provided. The grateful thanks of the department are due to all the various purchasing officers of the Surgeon-General's Office. Without such equipment, it would have been impossible to do the work that was accomplished.

The operating room was fitted up with two operating tables and an operating chair, gas and oxygen outfit, an instrument cabinet, dressing cases, etc. The sterilizing room was provided with an electric sterilizing apparatus, capable of sterilizing all dressings and instruments for the department. Each treatment room contained four places for examination and treatment of patients, with a wash bowl at each place serving as a cuspidor, and electric connections for lights. At the end of each room there was a place for the assistant in charge of the clinic to work. Each room was provided with a modern suction apparatus. The private treatment room was also well equipped and contained a suction outfit. The lecture room was provided with blackboards and a Barry tuning chair.

The school was particularly fortunate in possessing an unusually valuable collection of cut sections of the head, lent by Lieut. Col. Harris P. Mosher, M. C., and Lieut.-Col. William H. Haskin, M. C. In addition to these, there was a good supply of wet specimens of the Larynx, a gift of Lieut.-Col. C. W. Richardson, M. C., a fine collection of lantern slides of the accessory sinuses, the gift of Col. Hanau W. Loeb, M. C., of St. Louis, and a collection of excellent slides of the ear, a gift of Dr. B. Alexander Randall of Philadelphia. Without these collections, satisfactory teaching would have been impossible.

* Read before the Section on Laryngology, Otolaryngology and Rhinology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

CLINICAL MATERIAL

The clinical material was at all times abundant. At no time were there less than 1,200 patients, and there were often as many as 2,000 or 2,500 in the hospital. In addition to this, the various camps scattered throughout the park contained as many as 60,000 troops at times, and served as feeders.

THE STUDENT OFFICERS

Altogether, 110 student officers passed through the school. These were selected after careful examination by the director or his representative, and were only a portion of those who desired to take the course. On account of the limited time, it was impossible to admit beginners, only those showing evidence of real fitness being received; and these were not allowed to continue if they proved, after a short time, to be incompetent.

OUTLINE OF THE COURSE

The course was planned to run from four to six weeks, but from the fact that the War Department did not order the men away at the end of that time, it extended in many cases to eight and ten weeks. It was the endeavor to make the course as thorough as it could be made in the time allotted for it. It consisted of lectures and practical work, observation of operations, ward walks, and the performance of operations by the officer himself, as he showed his ability.

The lectures were given by the director of the department, by his assistants, and by the heads of other departments, including that of the School of Laboratories, School of X-Ray and School of Ophthalmology. Much attention was given to anatomy, which was taught with wet and dry specimens, lantern slides and on the cadaver. For practical work, the class was divided into small groups in charge of assistant instructors. Each student officer was provided with a head mirror and examining instruments, and required to make examinations and diagnoses himself. Each week, the subjects treated during the week were gone over in quiz by the director of the school. At the end of the course, a written examination was given, as well as a practical examination. The officers' ratings were based on the results of these two examinations.

A report of the ratings was sent each month to the Surgeon-General. Officers who had graduated satisfactorily from the school were assigned as assistants in the wards of the hospital. Those who showed themselves especially qualified were given temporary assignments as ward surgeons to the hospital, remaining in this capacity until they were ordered elsewhere by the War Department.

CONCLUSIONS

As already stated, the School of Otolaryngology was only a part of a comprehensive plan of graduate instruction for medical officers. Scarcely had this country entered on the war, before the pressing need of such instruction became evident to those in charge of the several training camps for medical officers. All those who had to do with these camps, in any capacity, were agreed that an unwarrantably high rating had been placed on medical education in this country. So far as otolaryngology was concerned, this was driven home with increasingly painful consciousness the longer the war continued.

At Camp Greenleaf, a board of examiners representing the various branches of medicine and surgery met daily to examine every student officer immediately on

his arrival. By this plan, every one representing himself as specially interested in any one of the specialties was assigned for examination by the director of the particular school. In this way, opportunity was given to ascertain the qualifications of several hundred men drawn from all parts of the country who claimed to be otolaryngologists or to have had more or less training in that specialty. The results of these examinations were as astonishing as they were disappointing. Whether the applicants for admission to the school had practiced the specialty for a few years or many, all, with comparatively few exceptions, showed a woful lack of knowledge of its fundamentals. With increasing emphasis as the weeks went by, the need of adequate and thorough graduate education truly to fit men for such work forced itself on those to whom the duty of making such examinations was assigned. Inquiry shows that out of the entire number who presented themselves, very few had had little more than a six weeks' course of graduate instruction. The all-important subject of anatomy was a closed book to them. With such a thing as the physiology of the nose, throat and ear, few had any acquaintance. Pathology, bacteriology and neurosurgery did not enter their field of knowledge. For most of them, the broad field of otolaryngology, with its intricate sidepaths, meant only the ability to remove tonsils and straighten septums.

This alarming lack of qualifications on the part of the average otolaryngologist, practicing in the cities and towns of this country, as demonstrated by the results of these examinations, served but to drive home with greater emphasis the need of comprehensive and adequate graduate instruction in otolaryngology. So long as the six weeks' course is given to any and all who are prepared to pay the prescribed tuition, apart from whether proper qualifications are possessed or not, so long will our country continue to be at the mercy of ill trained and uneducated specialists.

The deductions from the experience gained in our work at Camp Greenleaf may be summarized under three heads:

1. The desirability of admitting to a course like the one just outlined, only men properly qualified. Much of the failure of the various postgraduate schools, as now constituted, has arisen from the custom of admitting to the various courses all who were in a position to pay the prescribed fee. So long as a teaching institution is dependent for existence on the fees of the students, so long will this error exist. The majority of the student officers who took the course had already taken courses in postgraduate schools and regarded themselves competent to perform the more common operations on the nose and throat, but were found entirely lacking otherwise.

2. The importance of a graded course of instruction in both theoretical and practical work. In too many cases the student is in the habit of selecting what appeals to him and passing over anything else. The specialty of otolaryngology is so broad that the well trained specialist cannot afford to be ignorant of a single phase of it.

3. The value of full-time instruction. Instead of a hurried hour twice a week, the result of the exigencies of private practice, the instructor should give his undivided time from morning to night to the interest of the students. No greater need exists today in undergraduate or postgraduate medical teaching than that of full-time instruction. This can be secured only by releas-

ing the teacher from the requirements of private practice by giving him an adequate salary.

We cannot too earnestly and emphatically urge the need of a reform in our present methods of instruction. Never was the time so ripe for actively pushing a properly worked out program of graduate education. Such a program has been presented to this section by the committee having the matter in charge. It contains three all-important recommendations:

1. There should be a standardized curriculum extending over a period of at least two years, to be given at Class A universities or colleges.

The details of this curriculum have been carefully worked out. A consideration of it is not in order on this occasion, further than to say that it calls for both didactic and clinical instruction, the former to include a thorough training in the basic subjects, such as anatomy, physiology and pathology, covering a period of six months, to be followed by residence in some special hospital as intern.

2. The student should pass a comprehensive examination on the completion of the course.

3. A special degree ought to be conferred by the university or college. As a preliminary to this special instruction, the student shall have engaged in general practice for at least four years.

No graduate school dependent on fees of the student for support is in a position to carry out the curriculum proposed. The postgraduate school, as now constituted, has a distinct and extremely important function, that of affording opportunity for the graduate in medicine to "brush up" and acquaint himself with the most up-to-date methods and procedures. It is not suitably endowed to give the systematic instruction which we are outlining now. For this, proper endowment or affiliation with an adequately endowed or properly supported university is essential, in order that no consideration of financial return will affect the carrying out to the letter of the curriculum decided on. Such a graduate school should have means to put into operation what is now generally recognized as the *sine qua non* of any proper clinical teaching, that is, paid, full-time instruction. It is necessary only to mention it to condemn the present method of one hour of clinical teaching three times a week, the inevitable result of the demands of private practice, on which the teacher must rely for a living. Only the unsuccessful practitioner or he who is blessed with a private income can possibly be depended on to give a sufficient amount of time to clinical teaching to secure the results desired.

If the Committee on the Teaching of Otolaryngology can have your support, and that of other national societies, it is their earnest hope and expectation that within a few years a marked change for the better will be witnessed in the qualifications of those who enter this specialty. This section can do much in advancing the reform. It is violating no confidence to say that up to the present time the medical schools of the country have not been overenthusiastic in offering their support. Harvard, alone, under the leadership of Professor Crockett, has taken definite steps in conformity with these plans of education. A similar forward movement by the leading universities of the country is essential to the success of the movement. This can be brought about only by the active and vigorous backing of the members of this influential body of otolaryngologists, and this support on behalf of the committee we earnestly solicit at the present time.

ABSTRACT OF DISCUSSION

DR. JOHN G. BOWMAN, Chicago: Dr. Harris' paper is a keen analysis both of the need of specialization in otolaryngology and of the way to meet that need. Dr. Harris seems clearly to have in mind the chief principle which makes for specialization. That principle is the necessity of leadership. Out of 1,000 men, let us say, in otolaryngology there are ten who see exactly what the specialty means in relation to the science and the practice of medicine; and these men see also the practical steps by which specialization may wisely develop. Dr. Harris is one of the ten. The business of the ten is not only to state clearly the ideal to be attained. Their business is also to state with quite as much definiteness the first step and second step, and possibly the third step, which lead directly toward the ideal. We all have too much experience in problems of the kind before us to believe that we can attain the ideal merely from a mood of enthusiasm or from expressions of hope. The problems before us are two in number: First, what can be done to encourage higher specialization in otolaryngology among the men now practicing otolaryngology? Second, what can be done in the medical school to encourage and to bring about the requisite specialization in otolaryngology before the medical graduates go into independent practice? Both these questions need serious consideration. Answering the first question, it seems to me that careful and regular review on the part of otolaryngologists of their own successes and failures is the first essential. In other words, the otolaryngologists, let us say, should check up their own work at least once in each thirty days and analyze for themselves wherein they have succeeded and wherein they have failed. Such analyses will require, obviously, the keeping of careful case records and the use of clinical laboratories. Answering the second question, we must analyze the scientific attainments required in the practice of otolaryngology and then bring these attainments to the medical school curriculum. When you, the leaders in your specialty, become really determined to add, let us say, one year of special graduate work to the medical curriculum for the training of those who elect otolaryngology, you will win the cooperation of the medical schools. But you must be determined, for a half hearted effort, as things stand now, will scarcely receive a hearing among the medical schools.

DR. H. P. MONTAG, Boston: Dr. Harris' paper is definite and complete. Dr. Bowman gives us some practical help and puts some of Dr. Harris' recommendations into concrete form. Between the two we have had this subject covered very completely. I would, however, like to soften one point brought out by Dr. Harris. The figures quoted by Colonel Munson will go around the country from paper to paper, from society to society. They are correct, but I think they should be softened. I have not until now been soft in speech in regard to the war, but really I do not think that these figures should go just as they stand. In order to explain why I am softening, I will tell you how the men were picked. The men as they came in who were known to the Surgeon-General's Office, the older men of the different specialties, were at once sent to the base hospitals and if possible put in charge. The younger men were also sent, preference being given to the men who came from recognized special hospitals. These two classes did not give enough men and then the question arose how to train men, and it ended by sending a double staff to the base hospitals, because it was hoped that the first staff would soon go abroad and the second staff would take their place. Then we were told that we could not send any more men over. About this time the schools were opened and we began to send men to the schools, and by that time we had only the poorer men left. Now be a little considerate when you quote these figures. The figures are true, but use them as kindly as you can.

DR. D. J. GIBBS WISHART, Toronto, Canada: I cannot add much to what has already been said by Dr. Harris, but I want to make one point, and that is, that we will only get anywhere by the height of the ideal we have before us, and if as a profession in this country we desire to turn out men, to have men practicing who are a credit to the profession, we must have a high ideal of the great breadth of laryngology and what it stands for. Each one of us, in our own particular

sphere of action, by having such an ideal set before us, will do a great deal through our influence in our local society and in the communities with which we are connected and with the public generally in placing before these different bodies these ideals, and I want to emphasize the necessity of having these ideals as high as possible. To the fathers of laryngology in this country who went abroad and studied many years, we owe a great deal, but now we have coming a large number of men who have not been abroad and who are trying to enter the profession in order that they may derive certain benefits they think accrue to those who practice the specialties; but they are not aware, because we have failed to show them, of the demands to be made on them in practicing the specialties, and I would ask that you carry away with you from this meeting the determination that so far as you can do it in your own sphere you will help to raise these ideals and to show to your weaker brethren that there is something more in otolaryngology than simply the removal of tonsils or the resection of a septum.

DR. C. G. COAKLEY, New York: I think the fault is with the organization of our teaching, not only here but abroad. There is no place abroad, there is no place in this country, where a man can get the instruction as outlined by Dr. Harris; that is, the preliminary study by which he will be grounded in the whole work, in anatomy and physiology, for, say, six months before he goes into his special hospital. The able men who are turned out in this country adequately equipped are the young men who have been fortunate enough to have a service in a special hospital devoted to otolaryngology, whether in service one year or sixteen months or two years. These men come out practically equipped, they are good operators, but many times they lack that preliminary training, that thorough grounding in anatomy which is so necessary to enable them to do the kind of work which ought to be done by the 990 men instead of the ten. It ought to be comparatively easy to establish a six months' training course in several of our universities. It will need but little additional capital and endowment; it will not need full-time men of the very highest rank in the profession. The younger men who have recently completed their hospital training are the practical men. They will have several hours a day while they are accumulating their practice to devote to this type of work and would be very glad of the comparatively small remuneration necessary to enable them to do that work. These are the practical men to do it and the leaders can supervise the work. Establish such a six months' course in two or three cities and you will advance to a much higher plane in this country than anything that has existed here or elsewhere.

DR. JOSEPH C. BECK, Chicago: After my medical service terminated in Europe I thought, as Dr. Bowman said this morning, now is the time to do something along the line of future education, of development in special work. We know how many men would go abroad every year to get their education, and we well remember that we were informed very early in the war, when the Germans were ahead, that after this war the various clinics in Austria and Germany, Vienna and Berlin, would be closed to America. It was my idea to find a substitute or an improvement, for I believe it can be an improvement, along these lines of clinics and courses. I set to work in the country I was in at that time—Prague—to find out what they thought about it, and found the clinical profession anxious to do all they could. I was told we could organize a clinic such as they had in Vienna, and succeeded in doing so. I was then given permission by the Czecho-Slovak government to travel through the allied countries and see what was being done, and if possible organize an interallied clinic. I went to Rome, Italy, and found the same cordial reception and courtesy on the part of the clinical professors, who were anxious to do what they could. I succeeded in organizing a clinic there. I went to France, but found the work had already been put under way by Colonel Lloyd of New York, who had organized a school for military men as a forerunner to courses in civil practice. In London I found still greater advances made. I found that Sir St. Clair Thomson, Sir Arlunhot Lane and Sir William Osler had been working on this matter, having a

school in which they were teaching men in various branches. Coming home, I naturally reported to my own school, the University of Illinois, and presented the subject to them. My plan being a university proposition, I asked for a meeting of our faculty, presented the subject to them and they endorsed my proposition. Since I have been in Atlantic City I received a letter from a Dr. Franklin of London who informs me that an Anglo-Czecho-Slovakian committee is being considered to further the interests of our specialty in the Balkan countries and at the contemplated University of Prague.

SIR ST. CLAIR THOMSON, London, England: England is slowly waking up now that the war is over; we have one eye open and the other is slowly opening, and we owe this to America and Americans. Sir Arlunhot Lane, Sir James McKenzie and Dr. Bruce of Toronto came back from their visit to America last summer so impressed with their reception and what had been told them that it was only at the end of July we called a hurried meeting to consider what we could do. They brought us the message that Americans were willing to come to London if we could "deliver the goods," and that it was up to us to try to take the place of Vienna and Berlin as the Mecca for the student of medicine. The only good thing I have done in the matter is to design the title. At Christmas we realized that large numbers of American military officers were being demobilized and passing through London, some of them flocking to Oxford and Cambridge and Edinburgh, so we had to get to work in a hurry and establish what we called an emergency post-graduate course. We also have the building of a real post-graduate hospital for which the money is forthcoming. There is also a rumor that wealthy men from this side will build an American hospital in London, where the poorest traveler may go, and also, what we have nothing to equal on our side, a private hospital with what we call paying wards. What we all need is reciprocity, but the greatest good on earth will be to make the Englishman lose his insularity and to get our students to come over here and study in your hospitals and universities, to show the Englishman, of whom I am the *avant courier*, that there is a body so distinguished, so large and so hospitable as the American Medical Association.

SPECIAL POINTS IN ABDOMINAL SURGERY

EMPHASIZED BY MILITARY EXPERIENCE*

GEORGE W. CRILE, M.D.

CLEVELAND

The experience in abdominal surgery in the great war may be discussed under the following headings: (a) comparison between the intestine of the average soldier and of the average civilian; (b) the factor of exhaustion—the effect of cold and wet; (c) the time factor; (d) the comparative effects of lesions of the solid and of the hollow viscera; (e) combined thoracic and abdominal wounds; (f) the phenomena and treatment of internal hemorrhage; (g) the prevention and treatment of shock, before, during and after operation; (h) the anesthetic factor; (i) the incidence of bronchopneumonia after abdominal operations; (j) retroperitoneal infections; (k) the treatment of peritonitis; (l) operative technique, and (m) comparison with civilian abdominal surgery.

COMPARISON BETWEEN THE INTESTINE OF THE AVERAGE SOLDIER AND OF THE AVERAGE CIVILIAN

Soldiers whose general condition had not been too greatly impaired by exhaustion from fighting, by wet

* Read before the Section on Surgery, General and Abdominal, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

and cold, or by shock or hemorrhage showed a resistance to infection rarely seen in civilian surgery. I observed apparently as marked an increase in the firmness and the thickness of the muscles of the intestine of the average soldier as compared with the average civilian patient, as the leg or arm muscles of the soldier were larger and firmer than those of the civilian.

EFFECT OF EXHAUSTION AND OF COLD AND WET

Soldiers wounded after a protracted season at the front, especially if cold and wet, as was almost universally the case during the winter months, with their general resistance lowered by bodily fatigue and mental stress, bore penetrating abdominal wounds badly.

THE TIME FACTOR

The length of time between the receipt of the wound and arrival at a hospital was a vital factor. After the tenth hour the prognosis became progressively worse until the twentieth hour, when, as a rule, the established infection made operative measures inadvisable.

COMPARATIVE EFFECTS OF LESIONS OF THE SOLID AND OF THE HOLLOW VISCERA

Lesions of the liver and spleen were far less grave than lesions of the hollow viscera. Generally speaking, surgical intervention was not indicated for lesions of the liver or of the spleen, excepting for the control of hemorrhage. For the control of progressive hemorrhage from the liver, gauze packing proved preferable to attempts to suture. Badly shattered spleens were best excised.

Lesions of the large intestine resulted in a higher mortality than lesions of the small intestine. In cases of gunshot wounds of the small intestine, it was surprising to find to what an extent, in many cases, leakage was controlled by the contraction of the muscular wall. As to mortality, lesions of the stomach were comparable to those of the small intestine.

COMBINED THORACIC AND ABDOMINAL WOUNDS

Combined thoracic and abdominal wounds were especially grave. The practical point is that the thoracic approach is usually better than the abdominal approach, provided there are no perforations lower than the stomach as indicated by the entrance and the exit points.

OUTSTANDING PHENOMENA OF INTERNAL HEMORRHAGE

The two outstanding phenomena of internal hemorrhage were a mounting leukocytosis and a falling temperature; the treatment employed included operation, morphin and blood transfusion, the giving of fluids, and keeping the patient warm.

PREVENTION AND TREATMENT OF SHOCK AND THE ANESTHETIC FACTOR

The best treatment for hemorrhage and shock is heat and rest, fluids, morphin, and blood transfusion. Among the conclusions adopted by the Interallied Surgical Congress, acting as a sort of supreme court of surgery, were the following:

1. The anesthetic of choice is nitrous oxid-oxygen.

2. "For abdominal cases and for patients suffering from shock, local anesthesia may be employed in conjunction with the administration of nitrous oxid and oxygen."

Among the evidence offered in support of these conclusions, Major-Gen. Sir Anthony Bowlby presented the work of one of the most brilliant British military

surgeons, Capt. Douglas C. Taylor, and the work of the chief of the anesthetic service of the British army, Capt. Gregory Marshall. The following statement by Captain Taylor I am privileged to quote:

Until the summer of 1917, my colleague, Capt. G. Marshall, invariably gave ether for my laparotomies for gunshot wounds of the abdomen. No series of 100 consecutive cases showed a recovery rate of much over 50 per cent.

During the summer and autumn of 1917 I did 101 laparotomies for abdominal wounds, and nearly half of them were given nitrous oxid and oxygen, combined with infiltration of the abdominal wall with eucain and procain. The more serious cases, i. e., those with rapid pulse and low pressure, were nearly all done by this method.

Of this series, twenty-seven died at the casualty clearing station, and seventy-four were evacuated to the base. Of the latter there have been only two deaths, both from secondary hemorrhage, one from the kidney and the other from the rectum and the buttock.

That is, by the employment of anociation, Dr. Taylor's mortality rate was reduced from approximately 50 per cent. to 29 per cent. So far as I am aware, this is the best record of the war.

Captain Marshall, in turn, has demonstrated that patients may apparently do well during ether anesthesia but do badly afterward, while they do well both during and after nitrous oxid-oxygen anesthesia.

The experience on a large scale of the resuscitation teams from the Lakeside Unit, which served continuously throughout Field Marshal Haig's great offensives in Flanders in 1917, showed that in abdominal operations somewhat better results were obtained if, before the beginning of the operation, sufficient blood were transfused to permit a safe performance of the operation; and if, again, at the completion of the operation, an ample amount of blood, up to 750 c.c., were given. Furthermore, if a let-down appeared later, the transfusion might be repeated. Meanwhile, the advantages of comfort, rest, warmth, morphin and fluids were added.

INCIDENCE OF BRONCHOPNEUMONIA

In abdominal surgery, the general experience was that, during the winter months, there were more deaths from bronchopneumonia than from peritonitis. In certain winter campaigns, on account of the fatigue of the troops from heavy front line duty, from cold and wet and difficult surroundings, the incidence of bronchopneumonia was so high that operations were temporarily suspended.

RETROPERITONEAL INFECTION

In military, as in civilian surgery, retroperitoneal infections carried a higher mortality than intraperitoneal infections.

TREATMENT OF PERITONITIS

Military experience also emphasized the essential points in the treatment of abdominal infection established by civilian experience, namely: (1) nitrous oxid-oxygen as the anesthetic of choice; (2) anesthetized incision; (3) accurate, clean-cut operation to diminish both infection and shock; (4) adequate drainage; (5) Fowler's position; (6) vast hot packs over the entire abdomen, spreading well down over the sides; (7) 5 per cent. sodium bicarbonate, with 5 per cent. glucose by rectal tap, continued as long as it is tolerated; (8) primary lavage of the stomach, repeated only if indicated; (9) from 2,500 to 3,000 c.c. of physiologic sodium chlorid solution administered subcutaneously every twenty-four hours until the period of danger is

past; (10) in grave, acute peritonitis, morphin given hypodermically until the respiratory rate is reduced from 10 to 14 per minute and held to this rate until danger is past.

The technic that will deal successfully with the exhausted, infected soldier with a perforation of the intestine will be of equal value to the exhausted civilian patient.

Certain points in technic in contradistinction to general management may be mentioned:

1. Assuming good technic, as compared with a rapid operator a slow surgeon has a high mortality.
2. Sutures are easily tied too tightly.
3. No drainage is required in operations on the small intestine.
4. In operations on the large intestine, drainage may be used, but never in contact with the line of suture.
5. Retroperitoneal infected wounds should be treated by the Carrel method.
5. The abdominal wall may be divided in any direction with impunity.
6. In great emergencies, a temporizing fistula may be made by marsupializing a hopelessly damaged coil.
7. Although not every penetrated abdomen holds perforated viscera, every perforated abdomen should be opened.
8. I have seen patients whose abdominal wall had been torn wide open, and whose intestine was cold, covered with mud, and perforated withal, get well under the management outlined.

CONCLUSION

The principal experiences on which the foregoing summary is based were with the British in Flanders in 1917, and with the American forces in the Argonne in 1918. The outstanding conclusion from this experience is that the general principles which govern the successful handling of the problems of abdominal surgery are the same in military and in civilian practice. A good abdominal surgeon in military surgery will be a good abdominal surgeon in civilian surgery, and vice versa.

VALUE OF CONVALESCENT BLOOD AND SERUM IN TREATMENT OF INFLUENZAL PNEUMONIA*

HENRY F. STOLL, M.D.

HARTFORD, CONN.

The utility of the usual forms of treatment during the epidemic of influenzal pneumonia was early manifest. With a fatality much greater than our common pneumonia, it suggested the pandemics of old when "the pestilence stalked at noon day through the city, and the doomed inhabitants fell like grass beneath its scythe."

Though the causal agent was undetermined, it seemed that the serum of convalescents might possibly contain antibodies in sufficient quantities to influence favorably the course of the disease.

Serum from patients convalescent from scarlet fever was found by Huber and Blumenthal, Von Leyden¹

and others to be of some therapeutic value in that disease, and both experimentally and in human beings the serum of poliomyelitis convalescents is beneficial if used early.²

Richardson and Connor³ recently demonstrated that the serum of patients convalescent from measles conferred a certain amount of immunity.

We did not know at this time that convalescent serum had been used at the naval hospital at Chelsea, Mass., and just as we were starting the treatment, McGuire and Redden⁴ published their results.

Our cases were too few in number to determine fully the value of this form of therapy, and the occurrence of a slight epidemic of hemolytic streptococcus cases early in 1919 increased the difficulty of interpreting our results. Yet certain observations were made that may be of interest and from them certain conclusions seem warranted.

Fifty-six patients received injections of convalescent serum, convalescent blood, or both. One other patient had several treatments, but is excluded because he had a large empyema when treatment was instituted.

Since we at first did not have enough serum for all cases, and as the mild ones usually resulted in recovery without any special treatment, we thought the best test would be to treat only those patients who were seriously ill. As will appear, some exceptions to this rule were made.

According to their condition when treatment was instituted, the cases were divided into four groups. This grouping is only approximately correct, as prognosis, at all times difficult, is especially so in an unfamiliar and very fatal malady.

Group A, 10 per cent. of the cases. Very favorable; mildly toxic; small area of pneumonia; no cyanosis nor vomiting; urine negative.

Group B, 19 per cent. Toxic symptoms more marked; pneumonia more extensive; mind clear; little or no cyanosis; seriously ill but recovery probable.

Group C, 30 per cent. Seriously ill; prognosis poor but patient not moribund, beginning gray cyanosis; often delirium; usually albumin and casts in the urine; as a rule, several lobes extensively involved.

Group D, 41 per cent. Very seriously ill; cyanosis, as a rule, marked; usually delirium or stupor; extensive lung involvement, with a rising temperature, pulse and respiration.

In primary pneumonia the respiratory rate in general gives a good index of the seriousness of the infection. In influenzal pneumonia the patient may be very toxic and have a poor prognosis, but with respirations only slightly increased.

In a group of patients selected because of their serious condition, the mortality rate to be significant should be compared with a like number of equally sick untreated patients. So overwhelming was the epidemic that this could not be done. The mortality in 435 cases of pneumonia, including those patients treated with convalescent serum, was 52 per cent.⁵ The mortality of the serum-treated patients was approximately 45 per cent, but the prognosis was distinctly bad in over 70 per cent. when treatment was instituted. Twelve of the fatal cases were in Group D, three in

Group C, and in only one, a pregnant woman, did the prognosis seem fairly good. She aborted; the temperature reached normal, but death ensued (Case 8).

Of the favorable cases (Groups A and B) the mortality was less than 25 per cent.

In a few cases which ended in recovery following the use of convalescent blood or serum, it did not seem that the outcome was in any way influenced by the treatment. We accordingly have listed these as unimproved in the classification appearing below.

There was a difference of opinion among the medical officers at the hospital as to the merits of the treatment. Lieut. A. D. Rood,⁶ in charge of the general pneumonia ward, considered it to be without value. Capt. Sothorne Key, the ward surgeon of the officers' ward, thought highly of it. Major Randolph, chief of the medical service, felt that in some cases it was of real value. As the medical officer who was directing this investigation, I appreciated the fact that the favorable results obtained in the officers' ward were not duplicated in the general ward. The reason for the difference, however, was not apparent until the two groups were studied separately.

The accompanying table shows that in 80 per cent. of the patients in the general pneumonia ward the prognosis was poor at the time the serum was administered, and 60 per cent. seemed quite hopeless. In the officers' ward, on the other hand, the prognosis was unfavorable in 62 per cent. and utterly bad in only 22 per cent. The enlisted men had had their pneumonia 5.4 days when treatment was started, while the patients in the officers' ward had been ill only 3.9 days.

Lamb and Brannin,⁷ in studying the epidemic at Camp Cody, found that death occurred, on an average, at the end of 4.9 days after the onset of the pneumonia.

In the officers' ward, notwithstanding the fact that in 62 per cent. of the cases the prognosis was unfavorable, 72 per cent. of the patients showed definite improvement, while in the general ward only 17 per cent. were benefited.

RESULTS OF TREATMENT IN TWO GROUPS OF CASES, AND THE DETERMINING FACTORS

	Number of Cases	Condition When Treated*				Days of Disease	Definite Improvement Per Cent.
		A Per Cent.	B Per Cent.	C Per Cent.	D Per Cent.		
Officers and Staff	32	16	22	40	22	3.9	72
Enl. and N. C. O.	24	4	16	20	60	5.4	17

* A, B, C and D refer to the prognosis, A being very favorable, B, C and D increasingly bad.

All patients admitted to the wards for officers immediately came under the ward surgeon who was to have charge of them, and serum was frequently given within a few hours after admittance. All cases going to the

general medical wards first went to the receiving ward where after a careful examination and short period of observation they were sent to their proper destination. This was deemed necessary to detect the contagious diseases and to avoid filling up the pneumonia ward with various other acute respiratory diseases. But a disadvantage existed in that the pneumonia patients often did not arrive in the pneumonia ward till from twelve to twenty-six hours after admittance. When the cause of the difference in the results in the two wards became apparent, treatments were given in the receiving ward; but by this time the epidemic had nearly subsided.

It is noteworthy that all who have written on the treatment of influenzal pneumonia, irrespective of the agent used, state that good results are obtained only when treatment is given early; that is, within the first two or three days of the disease.

In twelve of our cases, treatment was given within forty-eight hours after the appearance of the pneumonia. One patient had a beginning empyema when treated. Of the eleven remaining, all except one (90 per cent.) recovered. The fatal case was a hemolytic streptococcus infection.

McGuire and Redden⁸ had an exceptional opportunity to observe the effect of convalescent serum in a small but virulent epidemic of influenza that developed among the officers and crew of the *Yacona*. Twenty cases of bronchopneumonia developed in eighty patients with influenza. All were promptly treated with serum, and all except one recovered.

In the first cases treated we used the serum obtained after allowing the blood to clot. Later we adopted the suggestion of Hartman⁹ and collected blood in sodium citrate solution. The serum thus obtained is plasma, but, for the sake of simplicity, is called by the more common name. Twenty-eight patients, in 59 per cent. of whom the prognosis was unfavorable, received a total of forty-nine injections of serum, and definite improvement resulted in half. Five of this group who did not improve developed a hemolytic streptococcus infection. One died from a pneumococcus Type IV meningitis.

In ten cases, seventeen injections of citrated blood of pneumonia convalescents were given. Six patients received only one injection, three received two each, and one was given five. In eight of the ten patients the prognosis was poor, in two utterly hopeless. The two last mentioned died, but five of the other six who were seriously ill definitely improved. The only patient not seriously ill who did not improve developed an empyema.

In eighteen cases at least one injection of convalescent blood and one of convalescent serum were given. The fact that all required more than one treatment

Chart 1. Importance of early treatment: Groups A, B, C and D refer to the patients' condition when treated, A being most favorable, D least so. The first column shows the percentage in each group. Broken line, patients ill 5.4 days when treated; 60 per cent. in Group B, of whom 17 per cent. only improved. Solid line, patients ill 3.9 days; only 22 per cent. in Group D, while 72 per cent. were benefited by treatment. Dotted line, twelve patients ill not over two days; 8 per cent. were in Group D, and 83 per cent. showed definite improvement.

would indicate that they constituted a more unfavorable group than the other two. The prognosis was bad in 83 per cent., and only 39 per cent. showed improvement.

The number of injections required to obtain the desired result is of interest. The chance of recovery is inversely proportionate to the number of treatments required. Of twenty-seven patients in whom marked improvement was noted, fourteen required only one treatment, five received two (the second injection was probably unnecessary in two cases), and five required three treatments. Only one patient received four treatments who was benefited, and two who received as many as five showed improvement. The last two had been ill a long time and received small amounts of serum. Had larger amounts been used, it is possible that fewer treatments would have been required.

McGuire and Redden¹⁰ used only one injection in one third of their cases, and of the remainder, two thirds needed only two. We used from 100 to 150 c.c. of serum; from 300 to 400 c.c. of whole blood was usually used, though in a few of our earlier cases amounts of less than 100 c.c. were employed. One of our most striking cases was in this group (Case 1). When blood was used, donor and recipient were always typed for agglutinins. This is not necessary with serum. Pooled serum was used in about one half the cases. We obtained the blood when the temperature had been normal about ten days, depending on how seriously ill the patient had been. Officers, their wives and nurses, gave their blood as willingly as did the patients in the general ward.

EFFECT OF CONVALESCENT SERUM ON THE SYMPTOMS AND COURSE OF THE DISEASE

Conscious patients in whom the influenza symptoms were marked, experienced relief, almost without exception, in a few hours. Headache and malaise would cease and a number of times severe vomiting of several days' duration promptly stopped (Cases 2 and 20). The detoxication was quite a definite thing. I talked with many officers and nurses during convalescence, and with hardly an exception they said they "felt entirely different" after the treatment. Cyanosis when not extreme would show improvement within twenty-four hours (Cases 3 and 4). One intensely jaundiced patient showed a remarkable clearing up of his jaundice within forty-eight hours after his treatment (Case 5).

The slight clouding of the sensorium frequently present was usually dissipated, but only occasionally did the patients who were delirious show a prompt clearing of consciousness. The rule was for the temperature, pulse and respiration to begin to fall, reaching normal in from thirty-six to forty-eight hours, depending on whether there was a chill. No change would be noted in the mental picture until from twenty-four to thirty-six hours later.

No improvement took place in the mental condition of one patient who had a complicating empyema and was much disoriented for weeks, though he received six treatments. He ultimately recovered. Ross and Hund,¹¹ using convalescent citrated blood, found that the temperature reached normal 1.5 days after the treatment and 9.5 days after the onset of the disease, while, with the untreated patients, the temperature did not become normal till the fifteenth day.

It was the rule that no extension of the pneumonic process took place after improvement in the symptoms occurred. A similar observation was made by McGuire and Redden. In a few cases, however, after a slight though definite improvement, a rapid extension followed with a fatal termination as a rule. One officer who showed such an extension into the only uninvolved lobe again showed prompt improvement and recovered when another treatment was given (Case 6).

Cowie and Beaven,¹² as a rule, found an increase in the signs following the use of typhoid vaccine.

The physical signs often would show no improvement until several days after the temperature, pulse and respiration had reached normal and all symptoms had subsided. In fact, the roentgenologist not infrequently would consider the patient still very critically ill, or even progressing, from a study of the daily negatives, when clinically he was quite convalescent.

After seeing the lungs at postmortem, it is difficult to understand how organs exhibiting so little normal tissue can continue to function, and it is even more remarkable that recovery sometimes takes place.

REACTIONS

Transfusions of normal citrated blood for various conditions are followed by a chill in about 20 per cent. of the cases.¹³

A reaction took place in twenty-three (16 per cent.) of our series of 140 intravenous injections. It is quite possible that a few patients may have had a slight reaction that escaped notice. The reaction was such as is seen following the injections of various foreign proteins. Within half an hour the patients feel chilly, and then have a shaking, followed by an elevation of temperature. In only one instance did the temperature go very high, and then 107 was recorded. As a rule, the temperature rapidly fell, reaching normal in about twelve hours.

Reactions occurred with about equal frequency with whole blood and with serum.

O'Malley and Hartman,¹⁴ using plasma, report a "response," usually a chill and sweat, in 75 per cent. of their cases, and the improvement was more prompt when the reaction took place.

RESULTS OF REACTION

In the great majority of instances, coincident with the fall in the temperature following the chill, the pulse and respiration dropped and there was marked clinical improvement. This took place with such regularity that we considered a chill a good omen. But in the case of four patients, all very ill, the reaction may have hastened their death (Case 7). It seems possible that the severe reaction in Case 3, reported by Cowie and Beaven,¹⁵ following an injection of typhoid antigen, may have hastened the fatal outcome, though they do not suggest this possibility. A severe reaction in a very sick patient is not to be regarded lightly. It may save his life, and it may hasten his death.

In the case of two of our patients who were treated at the same time, with serum a week old, marked flushing of the face accompanied the reaction (Cases 7 and 8). The serum was perfectly clear and sterile and free

from any preservative. With this exception, the serum used was rarely over two days old. The blood was never over twenty-four hours old, and as a rule it was used within twelve hours. Blood not used when obtained was put into serum at the end of twenty-four hours, or sooner, if the donor and recipient were not compatible.

Prior to a few years ago, it was assumed that the reaction resulting from the injection of an antigen was a specific one. The improvement in chronic arthritis following the reaction induced by the intravenous injection of typhoid antigen demonstrated that bacteria in no way responsible for the pathologic condition could cause a reaction that might be followed by improvement. Yet these "nonspecific" reactions may be more specific than at first appears. It is, indeed, quite possible that they furnish the incentive for the production of specific antibodies.

Beneficial results have been reported in various conditions employing a variety of foreign protein.

Cowie and Beaven¹¹ were able to produce a reaction in influenzal pneumonia which in several instances was followed by improvement by injecting typhoid antigen.

Lamb and Brannin⁷ observed improvement following the injecting of a variety of foreign protein, but only when a chill was produced.

Roberts and Cary¹⁴ employed a vaccine made of pneumococci, Types I, II and III, streptococci and staphylococci; and when a reaction was produced, improvement usually followed.

It is noteworthy that in 80 per cent. of our cases in which definite improvement was shown, there was no reaction which is suggestive of specificity.

Nineteen patients received injections of blood or serum from healthy individuals who had not had influenza or pneumonia. One having an empyema when treated is not considered. In five the prognosis was good (A and B), and 20 per cent. seemed benefited. This is in striking contrast to the 75 per cent. showing improvement in the same type of cases with convalescent blood or serum. In fourteen the prognosis was poor, and in 21 per cent. of these improvement followed. In one very sick patient the result was striking (Case 9). It is therefore evident that except in an occasional case the transfusion of "normal" blood is without benefit, with which opinion McGuire and Redden⁸ concur.

Ten patients received serum or blood from patients who had had influenza but not pneumonia. Leaving out of account one patient with a large empyema, there were nine to be reported on. The prognosis was poor in six. Slight improvement followed in one case, and in two others, in both of which a chill occurred, there was marked improvement (Case 11). In all, twenty injections of blood or serum of influenza convalescents were given, and in four (20 per cent.) a reaction occurred.

On the assumption that the pneumonia following influenza might be due to secondary organisms, possibly the pneumococcus, we decided to try the effect of transfusion from healthy adults who had not had influenza or pneumonia, and who had been vaccinated with the triple vaccine prepared at the Army Medical School.

Notwithstanding the fact that almost all of our pneumonia cases belonged to Type IV, we thought this

worthy of trial because Cecil and Austin¹⁵ found that vaccination against the first three types appeared to diminish the number of Type IV infections. Blood was obtained a week following vaccination, as, at that time, immune bodies are at their maximum.

In seven cases the "normal" immunized blood or serum was given, but in only one case did improvement follow (Case 12). This was a lobar pneumonia with a high leukocyte count, and as the serum was administered on the fifth day, it is possible that the falling temperature was the normal crisis. In this connection it is of interest that Cecil and Vaughan¹⁶ found that prophylactic vaccination with the pneumococcus lipovaccine did not lower the mortality in influenzal pneumonia.

Two patients with a hemolytic streptococcus pneumonia were given transfusion from patients convalescent from hemolytic streptococcus tonsillitis. One showed no improvement; the other had two injections, both being followed by a chill, and recovery took place (Case 13).

STUDY OF THE LEUKOCYTE COUNT

Uncomplicated cases showed the leukopenia so characteristic of the disease. A steadily rising count usually heralded the advent of an empyema. It did not seem that the degree of leukopenia afforded any trustworthy guide as to the prognosis, though a very low count indicates a general infection.

Notwithstanding that many counts were made, our records are not sufficiently complete to be of much value. It so happened that nearly all of the cases in which complete studies were made before and after injections proved to be hemolytic streptococcus cases.

Koss and Hund¹⁰ found that there was a rise in the leukocytes following the transfusion of convalescent citrated blood, which in some cases reached 24,000. A fall to normal was observed as further improvement took place. They do not state whether any difference was observed in the patients who reacted with a chill and in those without a reaction. An increase is commonly found following a protein reaction. In one of our cases the leukocytes rose from 3,300 to 23,000 following a sharp chill occasioned by the transfusion of convalescent blood.

In another case in which there was no reaction following the injection of 300 c.c. of convalescent blood, the leukocytes rose from 5,700 to 13,400 by the end of twenty-four hours. A patient who received 200 c.c. of "normal" serum without reaction or notable improvement showed the following count: before treatment, 5,100; first hour after, 5,100; second hour, 5,700; twenty-four hours later, 4,200.

An increase in the number of leukocytes was noted in some who died, while some showed a falling count. In others there was no change. Following three injections of convalescent serum given in one case during twenty-four hours without reaction but with well marked clinical improvement, the leukocytes rose from 3,000 to 11,500.

The intense congestion of the lungs that characterizes this malady affords an ideal site for the growth of various organisms, the most dreaded being the hemolytic streptococcus. The longer the patient is ill, the greater becomes the danger of the infection. It is perhaps significant that hemolytic streptococcus

14. Roberts, Dudley, and Cary, E. G.: Bacterial Protein Injections in Influenzal Pneumonia, *J. A. M. A.* 72:922 (March 29) 1919.

15. Cecil, R. L., and Austin, J. H.: *J. Exper. M.* 28:19 (July) 1918.

16. Cecil, R. L., and Vaughan, H. F.: *J. Exper. M.* 29:437 (May) 1919.

infections were more frequent among the patients treated with "normal" blood than among those receiving convalescent blood.

Of eleven cases in which convalescent blood or serum was given during the first forty-eight hours of the pneumonia, in one a hemolytic streptococcus complication developed. Nineteen patients were treated on the third or fourth day, and eight died. Seven came to necropsy, and five showed the hemolytic streptococcus as the predominant organism. On the other hand, Lamb and Bramin¹⁷ felt that the hemolytic streptococcus did not increase the mortality of influenzal pneumonia. We did not observe any difference in the results obtained with citrated blood, plasma or serum. Whole blood is to be preferred possibly on theoretical grounds, as the introduction of a considerable number of healthy blood corpuscles that will probably continue to function for some time might furnish material aid to the sorely taxed red cells of the recipient.

Cases of hemolytic streptococcus infections were fewest after the use of convalescent whole blood; but, as our series was small, too much significance should not be attached to it.

Specificity of action, which our cases suggest, is not borne out by the work of Lesné¹⁸ and his co-workers, who have been investigating the action of citrated plasma. They believe that it acts as a foreign protein, and they found that patients injected with "normal" plasma or with their own plasma did as well as when convalescent plasma was used. Their series was small, and they appear to have produced a reaction in nearly all of their cases.

When laboratory facilities are at hand, the use of whole blood is simpler and quicker, as it takes only a few minutes to determine the iso-agglutinins. Plasma is obtained by allowing the citrated blood to stand several hours; no grouping of recipient and donor is required, and the serum from several donors can be pooled, which is of advantage.

It does not seem necessary at this time to describe the method of obtaining the blood and administering the treatment, as this has been taken up in detail by several writers on the subject.¹⁹ To insure a supply of fresh serum, each patient when treated should promise to give some blood when convalescent.

SUMMARY

1. Fifty-six patients with influenzal pneumonia, in 70 per cent. of whom the prognosis was poor, were treated with the blood or serum of convalescent patients with a mortality of approximately 45 per cent.

2. Twelve cases were treated within forty-eight hours after the development of the pneumonia. One patient had a beginning empyema when treated; another developed a hemolytic streptococcus infection and died; and one other died. The remaining ten showed prompt improvement and recovered.

3. Thirty-two patients had been ill with pneumonia for an average of 3.9 days when treated, and 72 per cent. showed distinct improvement.

4. Of twenty-four patients ill 5.4 days when treated, 17 per cent. showed improvement.

5. Nine patients, six of whom were seriously ill, were treated with blood or serum of patients convalescent from influenza but who had not had pneumonia. Only two exhibited well marked improvement following the treatment, and both reacted with a chill.

6. Nineteen patients received transfusions of blood or serum from individuals who had not had influenza or pneumonia. No better results were obtained in the cases in which the prognosis was favorable than in the serious cases. Twenty per cent. seemingly were benefited.

7. Nine patients were given blood or serum from healthy adults vaccinated a week previously with triple pneumonia vaccine. In only one case, a lobar pneumonia with a leukocytosis, did improvement follow.

8. Sixteen per cent. of our patients treated with convalescent serum reacted with a chill and rise of temperature. With but four exceptions prompt improvement followed the reaction. In four critically ill patients, death was possibly hastened by the reaction.

9. In 39 per cent. of the cases in which definite improvement was shown no reaction was manifest.

10. Over half of the patients showing improvement required only one injection to obtain the desired results.

CONCLUSIONS

1. The transfusion of "normal" blood or serum is only exceptionally of value in influenzal pneumonia.

2. The blood or serum from individuals vaccinated against pneumococcus Types I, II and III possesses no advantages over "normal" blood in this type of pneumonia.

3. Too few patients were treated with convalescent influenza serum to warrant definite conclusions. The impression received was that it was less potent than convalescent pneumonia serum but of more value than "normal" serum.

4. The transfusion of blood or serum from convalescent influenzal pneumonia patients is occasionally of value though used as late as the fifth day of the disease. When used early, within the first three days, a distinct improvement in all symptoms is to be noted in the majority of cases. It seems to lower the mortality, shorten the course of the disease, and diminish complications.

5. The early employment of convalescent serum, therefore, appears to be a therapeutic measure of definite value.

502 5th Street.

TREATMENT OF INFLUENZA BY MEANS OTHER THAN VACCINES AND SERUMS*

JAMES B. HERRICK, M.D.

CHICAGO

This brief paper will be essentially an expression of personal opinion as to the treatment of influenza by means other than serums or vaccines. This opinion is based on an experience with the disease in the epidemic of 1889 and 1890 and the years immediately following, as well as in the epidemic through which we have just passed. Experiences of other physicians, as revealed by personal communication and by observation of their practice, are also laid under contribution. Many articles on the subject have been read, but no claim is made that the enormous mass of literature that has resulted from the visitations of this serious disease has been

17. Lesné, *Presse Méd.* 27:181 (April 7) 1919.
18. Compare footnotes 4, 7, 8 and 9.

* Read before the joint meeting of the Section on Pharmacology and Therapeutics, the Section on Pathology and Physiology and the Section on Preventive Medicine and Public Health at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

carefully studied or thoroughly digested. The task would be both discouraging and unprofitable, because so many of these articles are the result of superficial observation and limited experience; so many ignore the fact of the self-limitation of the infection and its natural course; so many conclusions are crude, and so many are reached by a mental process in which an optimistic credulity takes the place of the more desirable scientific skepticism.

Perhaps, however, the task would not be wholly unprofitable if it were to let us know more nearly where the profession stands today in the matter of drug and other treatment of influenza, and if it were to serve forcibly to bring home the lesson that as yet we have no specific treatment for the disease, no one or two drugs on which all physicians are agreed as to their preeminent value in prophylactic or active therapy.

No drug is known to prevent the occurrence of influenza. Many have been tried, but a review of the reports made by optimistic clinicians is far from convincing. A drug of this category is quinin, warmly advocated, though without adequate proof, by many Italian physicians, but by others of the same country regarded as without value.

Segregation of those who are ill and the prohibiting of public gatherings must lessen the number of contact infections. Perhaps it would be more nearly correct to state that such measures lessen the rapidity of the spread of the disease by lessening the concentration of exposures. The impression one gets from a consideration of the incidence of influenza as it has occurred in the camps and larger cities is that in spite of all practicable quarantine measures the epidemic goes through the populace sparing the immunes, but affecting the susceptibles, approximately 30 per cent., of the total number. Prohibition of public gatherings seems to spread the disease more thinly over a longer space of time. It may act also to postpone the occurrence until such time as the less virulent type is prevalent. By this diluent action fewer fatalities may result. Both these are desirable ends, and so these measures are to be encouraged.

Reports of clinical observations and experiments vary as to the value of the gauze masks. There can be no doubt that a properly constructed mask worn by the patient must lessen the danger of droplet infection of nurses, attendants and other nearby patients, and thus minimize the danger of carriage of the disease or of crossed infections. The masking of physicians and nurses acts in the same way, though not to the same degree. The suggestive effect of the mask, emphasizing care as to cleanliness, is not to be undervalued. The faulty way in which masks are sometimes constructed, the carelessness with which they are worn and the use of soiled masks are productive of no good and, at times, cause harm. The mask properly used has probably come to stay, though its exact value is far from determined. And such a clinical experiment as that in which the attempt was made to transfer influenza by the swabbing of the throats of healthy individuals with the nasal and throat secretions of influenza patients, without resulting transference of the disease, goes far to shake one's faith in the mask as a preventive measure against influenza.

In order to be convinced of the fact that there is no generally accepted plan of treatment, it is only necessary to see cases in consultation with other

physicians, or to read the abundant literature on this disease of the last six months, or to go back to the voluminous writings published after the epidemic of 1890 and the years immediately following. The utter lack of uniformity as to drugs recommended is the best proof that there is no one remedy of sovereign value. That this is the fact, not alone in the English speaking medical world, but in other lands as well, is revealed by a perusal of the medical supplement of the *Review of the Foreign Press* issued by the British General Staff, War Office. Take, for instance, the number for April, 1919, in which there are abstracts from recent French, Italian, German, Scandinavian and Swiss journals. A catalogue of the remedies advocated reads: intravenous injection of camphor oil, camphorated oil with guaiacol, intravenous use of mercuric chlorid, intravenous injections of hexamethylenamin, quinin in large doses, collargol, colloid gold, colloidal metals in combination with antistreptococcal serum, calcium chlorid, neo-arsphenamin, diphtheria antitoxin and tetanus antitoxin. Certainly some one has blundered in reaching conclusions.

There is, however, one feature of the treatment of influenza on which all agree, namely, the importance of early rest in bed and the continuance of such rest until fever, cough and other symptoms have for several days disappeared. It is a common experience for the patient who does not at once give up when attacked by the disease, or who leaves his bed early and attempts to go to work the moment he thinks he has the requisite strength, to suffer from a recurrence of symptoms, possibly to have pneumonia appear, or to be incapacitated on account of persistent cough, irritable heart or nervous and muscular weakness. A few days added to the period of rest would often save the patient from a protracted convalescence or prevent serious sequelae.

A sunlit room, plenty of fresh air and a light diet with a liberal amount of liquids should be allowed and enjoined. The bowels should be opened fully at the beginning of the illness and not allowed to become sluggish at any time.

One of the hardest things to do in the treatment of a serious, self-limited, infectious disease is to refrain from prescribing drugs merely because the diagnosis has been made. The self-restraint of the level-headed physician is likely to be swept aside by the thought of the possible grave consequences of the malady, and his accustomed good judgment is apt to be smothered in the semihysterical atmosphere of alarm that pervades the community during the visitations of the epidemic. He forgets that a large proportion of patients with influenza do not need a single dose of medicine. There should be no routine treatment according to which certain drugs are given at stated periods, whether or not there is a clear indication for their use. The treatment is really expectant, symptomatic and individualistic.

It was my lot to be in charge of the influenza isolation wards in the Presbyterian Hospital, Chicago, during the recent epidemic. There were about 160 nurses, members of the hospital personnel and medical students from Rush Medical College who were patients. The disease was vicious and severe; pneumonia and other serious manifestations were common. Of the 160 patients, only one died, a nurse. So far as I could learn, there had been no prophylactic vaccina-

tion or use of serum in any case; no treatment of this kind was instituted in the hospital. There were no standing orders as to drugs. No acetylsalicylic acid, phenacetin, digitalis, codein, quinin, atropin or other remedy was to be prescribed as a routine. Rest in bed from the very beginning of the symptoms, and for several days after the cessation of the symptoms, was the standing order. Liquids were given freely. I have wondered whether if I had used some vaccine or serum or other supposed specific I might not now be eager to get into print with my record of only 0.6 per cent. mortality. Nay, I should have been in print long before this. I merely have the satisfaction of knowing that no lives were taken by drugs (I think I am free of the charge in the one fatal case with extensive pneumonia), and that cautious conservatism gave Nature a chance to work a cure. We trust we helped her in her healing work.

The remedy that seemed of greatest value was digitalis. Without waiting for alarming indications of failing heart to develop in the way of feeble tones, rapid action, arrhythmia or dilatation, digitalis was given by the mouth, hypodermically or intravenously in small or large doses as need arose. I am sure that by its intravenous use several patients were very materially benefited, and that in some instances dangerous or even fatal heart failure was averted. I never saw harm result from its careful use, except that occasionally it induced nausea when given in large or frequent doses, as it necessarily had to be. Next to digitalis, the drug that seemed to me to be most helpful was opium—nearly always given as a hypodermic of morphin, or when the allaying of an annoying cough was the desired aim, in the form of heroin or codein. Pain, sleeplessness and severe cough have seemed clearly to indicate its use. The benefit from one sixth grain of morphin to the patient who, racked with cough and distressed by the pain of a pleurisy, has not slept for twenty-four hours, is too self-evident to need argument. There is too much fear of a hypodermic injection under these circumstances; fear both on the part of the physician and of the laity. Camphorated oil may be extremely helpful when there is a weak heart. In influenza in a patient who had been asthmatic and in whose chest there was much wheezing, I have seen good come from administering epinephrin. Hypodermoclysis or proctoclysis may be helpful. I think I saved one life by bleeding.

But I must be careful, or I shall lay myself open to the charge of having my pet drugs, or a treatment which I claim is curative. And to have favorite remedies which we talk about too much is to expose ourselves to the danger of believing in them more than is warranted by the facts. Even the quack comes to have a half-way belief in the curative powers of his methods. One ought not to be a nihilist as regards drugs in this disease; but no apology is needed for being a good deal of a skeptic as to the value of much of the therapy that is prevalent. Wholesale and indiscriminate drugging and the giving of huge doses is much too common. There should be a management of influenza as rational and simple as that of a developed case of typhoid fever, in which, today, in the hands of the intelligent physician and the enlightened public, drugs play a subordinate rôle. How much harm may be done by overdugging no one can estimate. But the danger is real and not imaginary.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. ROSENAU, FROST, PARK, CONNER,
ROSENOW AND STURDIVANT, MCCOY,
STOLL AND HERRICK

DR. AUGUSTUS B. WADSWORTH, Albany, N. Y.: The essential conditions under which the etiologic relationship of an organism to an infectious process is established have not been fulfilled with any organisms that have been isolated from influenza. We attempted to study this whole problem very carefully and thoroughly—bacteriologically and pathologically. At first we failed to find the influenza bacillus in the cases studied, but later, with improved technic, we were able to establish its presence. At first these cultures apparently were all similarly variable in morphology and uniform in their hemophylic cultural reactions. The thermal limits of growth were found to be quite constant and uniformly low, as compared with many other pathogenic species, ranging between 40 C. and 41 C., and nearly all of the cultures failed to grow above 40.5 C. By further study it was found that twenty-two cultures of influenza did not acidify any of the carbohydrates; forty cultures acidified dextrose; and sixteen other cultures formed both gas and acid in dextrose. The toxicity of these cultures varied greatly in animals. Infections seldom developed in them. When injected into the trachea of rabbits, the cultures of the influenza bacillus and their filtrates frequently gave rise to considerable lung reaction and lesions quite as extensive as those induced by pneumococci. In some instances, the lung lesion was more marked when both pneumococci and influenza bacilli were injected. Many of the lesions found in the rabbits' lungs after injection with pure cultures of the influenza bacillus resembled very closely lesions found in the lung at necropsy in cases of human influenza. But the most toxic reactions of purely hemorrhagic pneumonitis so characteristic of the lung involvement of human influenza were not marked in these experiments in rabbits. Twenty-four hours after tracheal inoculation, the influenza bacillus was recovered from the lung lesion, but at the end of forty-eight hours no organism was obtained. Evidently the rabbit is relatively insusceptible to infection with the influenza bacillus. In our study of the practical value of the vaccine of the influenza bacillus, we made investigations in thirty-three state institutions. In twenty-eight we found that a greater number of cases of influenza developed among the vaccinated than the unvaccinated after vaccination had been started. In another institution the number of cases that developed among the vaccinated was 1.24 per cent. and 1.1 per cent. among the unvaccinated; and in another, among the vaccinated 2.48 per cent. and 4.2 per cent. among the unvaccinated. In another institution 461 inmates were vaccinated. Dr. Park's laboratory failed to find the influenza bacillus in more than three inmates. The institution was very carefully quarantined during the epidemic, and no influenza developed for three months. Then there was an outbreak of 203 cases, 166 cases developing among the vaccinated inmates and thirty-seven among the unvaccinated inmates. The cases that occurred among the unvaccinated included those that were admitted to the institution after vaccination had been started. Of thirty-eight cases examined, thirty-two had influenza bacilli in the discharges.

DR. ANNA W. WILLIAMS, New York: I wish to emphasize one point in regard to the etiology of a pandemic disease, and that is, that there is no necessity whatever for wasting any time at first on determining whether an organism suspected of being the etiologic agent of the pandemic is pathogenic or not. The important thing is to decide whether or not we have one type among the strains isolated. Until this point is settled in the affirmative we need not pay any attention to the so-called postulates of Koch. If the pandemic is a true microbial pandemic, that is, starting from one cause and spreading through that cause, we should be able to prove that there is one variety or type of microorganism that is responsible for the pandemic. Of course, we have to determine what test we must choose to prove this. Up to the present, we have decided that we will accept the agglutination test with the absorption of agglutinins for the

test of type until somebody proves that this test is not the final test. We have shown that all the influenza strains we have isolated do not respond to this test; that practically each strain is a law unto itself, with the exception of strains picked from one case. Now, if it is true that that test can be accepted, and if it is true that by our methods we have not missed a pandemic strain, or that the strains do not readily change in their power to produce the same agglutinins, then the influenza bacillus has nothing whatever to do with the initiating cause of the epidemic.

DR. EDWIN R. LE COUNT, Chicago: Certain salient facts stand out prominently in connection with this disease. One of the most astounding is the way in which it spread. It has been compared to measles and other similar eruptive fevers, and it may be that if the human race was as susceptible and less immunized to measles than it is, and we should have measles suddenly thrown on us, measles would spread over the world in a way similar to the spread of influenza, but outside of such a conception of measles, or some other infectious disease, we have nothing to compare influenza with, in the way in which it has extended. Therefore, it does seem that its causation should be in a way quite unique also. The clinical manifestations are correspondingly fairly clear, and through the investigation of MacCallum, Goodpasture and Wollbach we are gradually getting somewhat of a clear idea as to the changes peculiar to the disease. Among the changes that do occur, there are certain features of the lung alterations that are conspicuous. One has been noticed by all who have studied these conditions in dead bodies, and that is the exceedingly great wetness of the lungs, and the way in which the fluid of the blood runs out into the pleural cavities. In the earlier part of the treatment, a mistake probably was made in withdrawing such fluids from the pleural cavities, as it amounted to continued bleeding at intervals, which probably did harm. Later, I have understood, this treatment was somewhat abandoned.

Microscopically there are also a few features that are characteristic. One is the thin layer of fibrin in the minutest air passages. Such a limitation of fibrin to the lining of the air sacs is also rather unique in the histology of lung inflammations. About twelve or fifteen years ago an epidemic of what we called ordinary lobar pneumonia or lung fever spread over this country. Many thousands died in a few months. Since the epidemic of influenza last fall, we saw practically none of that old type of lobar pneumonia. Lobar pneumonia in an anatomic sense was observed during this epidemic of influenza; but not lobar pneumonia in the full clinical sense. The lobar pneumonia we saw is post-influenzal and is due to secondary infection; moreover, the lobar pneumonia observed during the recent epidemic has been unlike that of twelve or fifteen years ago and of even more recent years, different anatomically in at least one noteworthy way: the absence of a heavy "shaggy" precipitate of fibrin in the pleural cavity.

DR. HENRY ALBERT, Iowa City, Iowa: Dr. Frost stated, I believe, that we have no evidence of immunity against influenza. I should like to cite an instance in which I believe we have very good clinical evidence of the existence of such immunity. A state institution at Mitchellville, Iowa, was investigated by our epidemiologist, Dr. Hamilton. This institution had a population of 180. The inmates were housed in six different cottages, but all received instruction in the same room. Early in October, 1918, in connection with the general epidemic, the disease gained a foothold in this institution. The administrative officials immediately isolated all the affected persons. Inmates of only three of the cottages were exposed, and the disease was entirely limited to the inmates of these three cottages. Seventy-six cases occurred at this time. As a result of very careful isolation, no further evidence of the disease appeared until two months later. At that time, one of the teachers was given permission to leave the institution for a few days. She returned with the beginning of an attack of influenza. In the course of a few days another epidemic appeared, to which every person in the institution was exposed. During the second epidemic, there were eighty-two cases of the disease, but not a single instance of a recurrence of the disease

among the seventy-six who had had the disease during the previous epidemic. Of the total population there were only twenty-two, or 12 per cent., who did not contract the disease during either of the epidemics. It seems to me very significant that during these two epidemics, out of a population of 180 persons, there was not a single case of recurrence during the second epidemic and I cannot help but think that it must be due to the development of immunity.

DR. ALEXANDER LAMBERT, New York: I was interested as I heard the other speakers refer to the difference in the clinical character of the pneumonias as modified by the recent epidemic. Perhaps, the experience with the pneumonias before the epidemic of 1889, during 1889, and during subsequent years, and in this epidemic may be of some interest. When I was in the hospital in 1885, 1886, 1887 and 1888, the pneumonias were clear-cut lobar pneumonias, very few of them bronchopneumonias. In 1889, as the influenza epidemic came to New York City, there were the same unusual pneumonias as in this last epidemic, with the same sodden kind of lungs. The pathology was clearly stated and taught by Delafield afterward, that the lungs showed a maximum of congestion and a minimum of exudation, and he further pointed out at that time that these were bronchopneumonias, but they did not differentiate the bacterial flora. They believed then that the pneumococcus caused them all and the streptococcus was not differentiated. Nor was it until 1892 that the description of the influenza bacillus was brought out. In 1892, within a few days after Pfeiffer's article was published in New York, I separated out the influenza bacilli from Delafield from some of his patients. The pneumonias for four or five years remained in New York, queer and patchy as if they were mild dying out types of influenza. They later became more the pure lobar type, and that continued through quite a while. Later, in 1901, an epidemic of grip appeared, and the bronchopneumonia came back, and the lobar type seemed to disappear again. Five or six or seven years ago the type returned to the clear-cut lobar type, and again it has returned to its predominating bronchopneumonia type. The differentiation this time which is helping to solve the problem much more clearly and intelligently is the differentiation of the primary and the secondary infections, the differentiation more clearly of the influence of the various bacteria, and particularly of the serious influence of the streptococcus. In studying the various types with the roentgen rays the pathology was clear and easy to understand.

DR. H. B. WOOD, Providence, R. I.: One important factor was the hemolytic infection of the throat in army camps throughout a number of states during the summer of 1917. A house-to-house canvass in five towns in New York state showed that about 85 per cent. of the persons closely exposed to the infection contracted the disease. In other words, what we call influenza has about the same infectiousness as measles. Sex had absolutely no effect. The people contracted the disease according to their opportunity to exposure.

DR. SOLOMON SOLIS COHEN, Philadelphia: One may agree thoroughly with Dr. Herrick's philosophic principles, yet differ with his application of them. That different remedies are advocated for one malady by no means implies that all are worthless. All may be helpful under given conditions, or even if two are useless, the third may be good. The point is, that in a matter not susceptible of experimental proof, but depending on individual observation and therefore virtually a matching of opinion against opinion, we cannot condemn, offhand. It is true that there is among the younger teachers today no general agreement on the proper method of treatment, other than serums and vaccines; but in the epidemic of thirty years ago there came to be general agreement as to what was useful, what was useless and what was harmful. Antipyrin and acetanilid were at first advocated by great authority, but their deadliness was soon recognized. Unfortunately, in Philadelphia at least, that lesson was forgotten. If I may judge from what I frequently heard in the consultation room, there was a widespread tendency to use two very harmful drugs, acetylsalicylic acid and acetphenetidin. The peak of mortality in Philadelphia shown on the charts resulted from many factors, among others, the great industrial population drawn from all

over the country, the crowding and promiscuous visiting in certain quarters, the lack of doctors and nurses. But it may have been, in part, owing to this bad practice. Not that every one died who received these drugs; quite a number survived both the disease and the medicine; some, no doubt, to suffer later from weakened heart and nerve depression. But in the majority of the cases in which they were used, these drugs deprived the patient of his chance to recover. Of that, I have no doubt. Salicin and certain of its derivatives, namely, sodium salicylate and quinin salicylate and cinchonidin salicylate (not aspirin, the acetyl-salicylic ester, remember—that is a dangerous cardiovascular depressant) were very useful, not as specifics, but as aids. Quinin dihydrobromid and quinin and urea hydrochlorid were also helpful, not only in cases which developed pneumonia, but in preventing pneumonia. DaCosta used to tell us that influenza is "at once the least fatal and the most fatal of all diseases." Of itself, the least fatal; in its complications and sequelae, the most fatal. If one thing has been brought out above any other in this discussion, it is that influenza is not merely a mixed infection, the term is not sufficient. Nor are the death dealing organisms merely secondary invaders. Influenza is a malignant symbiosis and must be studied from that viewpoint before we can understand its pathology and epidemiology. There is one drug that antagonizes the influenza poison, opposing this vital depressant throughout its whole range of influence. It is itself a dangerous drug if used indiscriminately; but it is helpful if used properly. That drug is coca, and its alkaloid, cocaine, used with due caution and under proper indication.

DR. HYMAN I. GOLDSTEIN, Camden, N. J.: It is very fortunate for Dr. Herrick to have had the more or less unusual opportunity to treat most of his 160 patients from the very beginning and in a hospital. I would like to ask Dr. Herrick what he would do under the usual circumstances with which general practitioners are confronted. In attempting to prevent the numerous deaths which Dr. E. C. Rosenow told us resulted from the secondary complications, are we justified in using the vaccine? I think we are justified in using vaccine, even if we do not know the specific cause of influenza, as a preventive and therapeutic measure against the complications. We have not a "cure all" or "sure cure" for all cases of any one disease. But are we justified in doing away with the use of mercury and arsphenamin in syphilis because it is not a cure in all cases? Digitan (digituratum), quinin dihydrochlorid, caffeine and coden were used symptomatically with considerable benefit to my patients. Benzyl benzoate relieves the pertussis-like cough so often heard in this epidemic. We must make the best use possible of what we have and, of course, we hope that our experts will eventually give us something definite with which to work.

DR. FREDERICK T. LORD, Boston: There seems to me no ground for the belief that a vaccine in the treatment of disease is of any value whatever. Vaccines may be of use in prophylaxis, but they have never been shown to be of value in treatment. Regarding the use of convalescent serum in the treatment of influenzal pneumonia, the presence of protective substances in the blood at the time of or after the crisis in lobar pneumonia has been established, but they are not constantly demonstrable. In ordinary lobar pneumonia, therefore, treatment with convalescent serum can hardly be expected to be followed by any very striking results. Stress has been laid on the favorable symptoms resulting from the use of convalescent serum. In a disease so variable in its symptoms as influenzal pneumonia one may readily fall into error in a judgment based on favorable symptoms following the administration of serum. Only a judgment based on mortality should count, and also that one must take into account in that judgment the very variable mortality existing during the epidemic. In one of our camps the figures indicate that the mortality from influenzal pneumonia was at one time 51 per cent. In the Students Army Training Corps at Cambridge the mortality was 8 per cent. Among sixty-one cases in the civilian community the mortality was as low as 3.2 per cent, the figures being gathered from civilian physicians. In view of this variability in mortality, it would be highly undesirable to base any final judgment

regarding the value of the method on any other than series of serum treated cases controlled by a simultaneous series not so treated. At the Massachusetts General Hospital we had twenty-three patients who were treated with convalescent serum, and of this number we lost six. At the same time we had twenty-five controls and we lost three.

DR. ALBERT E. ROUSSEL, Philadelphia: Experience in the 1889 epidemic and the present one, from the similarity of the clinical symptoms, would lead one to appreciate the fact that we were dealing with the same disease and probably due to the same organism. The second point of appreciation in both of these experiences is the fact that uncomplicated influenza has practically no mortality. It is true that the number of cases of complications of the respiratory tract were numerous in this present pandemic, and disproportionate to the first, but uncomplicated influenza practically cures itself, and there is no question at all that the existence of large bodies of troops in and around cantonments invited probably the same combination of organisms and, on the other hand, the diminished resistance of the civil population caused by underfeeding and worry made this probably the most intense and virulent type of influenza that we have yet seen and, possibly, that we may ever see. The proportion of jaundice was rather larger than has been mentioned. Possibly 4 per cent. of the cases of pneumonia showed jaundice, and almost all the patients exhibited tenderness in the neighborhood of the gallbladder, and it is a question whether there were not many cases of catarrhal cholecystitis, and a number of other cases of a more severe type. Among 186 hospital cases of pneumonia, excluding the deaths that occurred within twenty-four hours, the mortality was a fraction of more than 25 per cent. On the other hand, I had at one hospital thirty-five cases of influenza among the interns and nurses with six cases of pneumonia, and all got well, because they were taken care of at the proper time. As regards drugs, I think bicarbonate of soda, in addition to the physiologic sodium chlorid solution, is of very considerable value. In the pneumonia cases, about 8 per cent. showed albumin urea, and about 4 per cent. distinct nephritis.

DR. WILL WALTER, Chicago: My interest in this subject is from the viewpoint of prophylactic inoculation in its relation to the upper respiratory tract. I can enlighten Dr. McCoy as to the bacillus "septus," as I did a research about fifteen years ago after a visit to Wright's clinic and laboratory, where we studied *Bacillus septus*, which had been presented as a cause of acute rhinitis by Dr. Allen of London. I reported on 100 of 300 cases and analyzed the results. My research covered the bacterial flora of the upper respiratory tract and *Bacillus septus* was found in slightly more than 55 per cent. of my cases of acute rhinitis. Since that time I have not seen it, but it is still reported in English literature. It belongs to the diphtheroids. I took the liberty of changing the name of this bacillus to *Bacillus segmentosus*. It is a wedge shaped segmented organism tending to palisade formation. It is mentioned in the last edition of Jordan's textbook on bacteriology. Dr. McCoy's records, so far as they relate to preventive inoculation, show a violation of the fundamental principles laid down by Wright, who always was very emphatic and still insists on the postulate that if you are going to do preventive inoculation in the presence of an epidemic you must use very small doses—infinitesimal doses. In the cases I have seen reported by Dr. McCoy as failing to show results, enormous doses were given, and not only that, but they were repeated on the third and again on the fifth day. This would be the very method to bring about a negative phase and therefore to increase the susceptibility of the patients to the organisms against which we are inoculating. It must not be forgotten that this is done not to prevent influenza, the cause of which is unknown, but to immunize, as Dr. Rosenow says, against the known organisms which kill.

DR. M. K. WYDER, Albuquerque, N. M.: Observations are very misleading. I use the prophylactic vaccine. I used it in a girls' boarding school in which I immunized, or at least attempted to immunize, the pupils, teachers, etc., and at the same time we established and enforced a complete

quarantine. There were eighty people in that institution; not a single case of influenza developed. One mother insisted on being admitted to visit her daughter. Being refused, she took the girl home. In less than a week that girl was dead from influenza.

DR. WILLIAM C. WOODWARD, Boston: Reference has been made to the influence of the closing of places of public assemblage and of the wearing of masks. I think, however, we may adopt a more nearly universal preventive measure that will tend to prevent not only influenza but also pneumonia, whooping cough, measles, diphtheria and diseases of the respiratory tract generally. We must learn to look on the discharges from the nose and throat as essentially as dangerous as the discharges from the urinary tract and the digestive tract. We must take the same precautions to prevent the transfer of such discharges from person to person that we take to prevent the transfer of fecal matter and urine, not merely when persons are sick, but continually, if we are going to control or do away with diseases of the respiratory tract. We must seek not only to control these mucous discharges in public places, but also in private life, at home, in places of employment, and so on. In short, we must at all times and all places take the same precaution to prevent the interchange of mucus and other secretions from the nose and the throat that we take to prevent the interchange of urine and fecal matter.

DR. C. C. BROWNING, Los Angeles: There is an element which I have not heard mentioned here that possibly may enter into some of the discrepancies which apparently characterize the statistical data in connection with this disease, the difference in the virulence of infection, or the acquired resistance of individuals of different communities. At Fort McArthur, during the earlier period of the epidemic on the Pacific coast, we received sporadic cases of influenza, about twenty-four cases from October 20 to 26, all of which came from the more or less thickly populated districts. These were of moderate severity; two cases of bronchopneumonia developed with no deaths. October 27 we received about 800 men who came from the mountainous districts and from the ranges in the West, men who were accustomed to outdoor life and had not been in crowded communities. Of these men forty were suffering with acute influenza. Within the next three days about 115 had been received into the hospital. Of these eight died within twenty-four hours of the first manifestation of symptoms; eleven died within forty-eight hours and twenty-eight died later. We learned from friends who visited the sick that the death rate was not larger among these recruits than among the families at home. Was the infection increased in virulence by reason of the persons having been accustomed to contact with the more common infectious organisms?

DR. H. H. COONS, Los Angeles: The epidemic reached us at the base hospital at Fort Sam Houston about October first. We used all the remedies recommended without avail. Then I began using the vaccines, very carefully at first, because vaccine therapy was not recognized as a treatment by the profession generally. In certain wards we got very good results. Almost uniformly within thirty to thirty-six hours after an injection of vaccine sufficient to get an initial rise of temperature, there was a very marked decline, better respiration, lessening of cyanosis and, in most cases, an improvement in the general condition of the patient. I did not suggest it as a specific but as an adjunct. We protected our patients from draughts and we put them to bed. We gave them fresh air, but not at the temperature of outdoor air. In the wards where I used vaccine the mortality rate in pneumonia was under 7 per cent. In the wards where we did not use vaccine but used all known precautionary measures, the mortality was 18 per cent. Approximately 100 patients were treated with vaccine. A great many more than that were not treated with vaccine.

DR. W. A. BASTERO, New York: There is no evidence whatever that more acetylsalicylic acid and acetphenetidin was employed in Philadelphia than in New York or Boston or any other city; nor was our death rate any different, except that it was worse. A large number of patients who recov-

ered had had very large doses of these drugs; others died, as did some who had had small doses.

DR. E. C. ROSENOW, Rochester, Minn.: The vaccine which we used was made to contain as soon after isolation as possible the bacteria isolated in influenza and the accompanying pneumonia together with type pneumococci. It contained, as we found months later, a high percentage of strains of green producing streptococci which, according to their serologic reactions, appear to bear etiologic relation to this disease and with which the picture of influenza has been closely simulated in animals. The lowered death rate and even the diminished incidence of recognizable influenza and the milder attacks noted in persons inoculated over that in the uninoculated, wherever the vaccine was properly used, is thus to be expected. A degree of protection from the use of this vaccine is just as rational, in the light of the newly discovered facts, as is the protection following prophylactic vaccination with pneumococci and other vaccines. The difficulties in evaluating the results, as pointed out by Dr. McCoy, have been considered and the sources of error eliminated. The immunity appears to be of relatively short duration, there being a falling off in six weeks to two months. The results recorded, however, represent observation extending over a period of from three to six months. Revaccination, consisting of one injection of the middle dose every six weeks to two months, while the disease is prevalent or as new waves appear, is therefore to be recommended. Averaging all the results obtained, it appears that the incidence of influenza was about three times as common and the death rate five times as high among the uninoculated as among the vaccinated persons.

DR. JAMES B. HERRICK, Chicago: Dr. Goldstein asked a question as to what is a general practitioner, deprived of the opportunity to put his patients into a well-managed hospital, to do. I think that what he should try to do is to get hold of his patients as early as possible, insist on the patients going to bed, make them stay there until well and not to overdrug them. I have been very much impressed by the harmfulness of many plans of treatment. That is why I have not used the vaccine or serums. I am not on principle opposed to them, but I do not think that as yet we have the proof that they are helpful. They may even be harmful. And so I say that the general practitioner should, if possible, get his patient early and give him some general line of treatment that has at least the virtue of harmlessness. The patients that came into that same hospital from the outside, into the same ward, under the care of the same doctors, with the same nurses, the same hospital assistants, the patients that came in on the second, third and fourth days of the disease, often with pneumonia, died, with a mortality which was so large that I hesitate to confess it. If those patients had been got hold of earlier, in my opinion, more of them would have recovered.

"Patent Medicines" in Venezuela.—At its session of March 27, the Academy of Medicine of Venezuela approved an opinion prepared by its permanent secretary, Dr. L. Razetti, as to which "patent medicines" should be considered as scientific preparations and which should be considered as commercial preparations. The report says: A "patent medicine" or rather "pharmaceutical specific" is a preparation the formula of which does not appear in any Pharmacopœia, and fulfills the following requisites: it is inalterable; has true merit, either on account of its form, its mode of preparation, its novelty or its composition; it is manufactured on a large scale and properly put up for sale; it has a rational name that indicates its chief components, and in no case based on its therapeutic properties; it gives on its label the name and quantity of each of the active substances contained in each dose; and it has been examined and approved by the National Office of Public Health. Those fulfilling these conditions may be considered as scientific preparations capable of answering therapeutic demands. Those that do not comply with these conditions should be considered as commercial preparations and their use should be forbidden for the benefit of the public health.

TREATMENT OF THE SEVERE VOMITINGS
OF EARLY PREGNANCY *FRANK W. LYNCH, M.D.
SAN FRANCISCO

It is difficult to estimate the frequency either of the ordinary morning sickness or of the serious vomitings, since both occur more frequently in America, France, England and Russia than in Germany, a fact which has been emphasized by those who see only a neurotic factor for its causation. Horwitz in Petrograd (1883) reported a history of some form of nausea and vomiting in 84 per cent. of his cases (morning sickness); Giles in London (1893) found 47 per cent.; and Gerst in Paris (1903) noted it in 66 per cent. I have found similar histories in 45 per cent. of 500 of my recent clinic cases at the University of California; 123 of 249 primiparas and 103 of 251 multiparas giving a history of nausea and vomiting, while in 46 cases, or 9 per cent. of the same series, there was a history of nausea without vomiting. In 500 private cases, exclusive of those referred for treatment of vomiting, 58 per cent. gave me a history of nausea and vomiting. It is even more difficult to ascertain the frequency of the serious types.

The small percentage of serious cases in Germany is quite remarkable. Carl Braun stated that he had not seen a fatal case in a series of 150,000 pregnancies. Similar statements are made by Hohl, Lomer, Frank and Strassman, although Guenot (1863) collected from the French literature forty-six fatalities in a series of 118 cases of pernicious vomiting and McClintock (1872) reported fifty fatal cases in England. Yet even as recently as 1914, Bondy reports only twenty-one cases of pernicious vomiting in 10,000 obstetric cases in Breslau and quotes Baish's series of twenty cases in 20,000 cases in Munich, and von Herf's report of thirty cases in 17,000, expressing his surprise that his cases were observed in married and multiparous women since he had been of the belief that the condition was apt to occur only in illegitimate primiparas. Yet these figures may not give a correct idea of the incidence of the disease in German countries since they are drawn entirely from hospital experience, and few believe that Pick's frequency of one case in 1,000 obstetric cases in Berlin represents the true frequency, since nearly every practitioner of experience here has met with several serious cases. In this country, Williams states that he observed only two cases in 5,000 clinic cases in his service at Baltimore, although he had studied comparatively large series in private cases during the same period. In 2,750 clinic cases at the University of California Hospital, fourteen entered for the treatment of vomiting, nearly all presenting during the last three years.

ETIOLOGY

Little is known of the etiology of this condition. Many factors have been urged as causative but do not stand careful scrutiny. A careful survey of the facts in hand forces one to conclude that, under certain conditions and in some way at present unknown, the

maternal organism is sensitized to vomiting by the state of pregnancy. This conclusion seems rational because, after the exclusion of chronic appendicitis, ulcer and other stomach and intestinal conditions which cause vomiting even in the nonpregnant woman and which may consequently be a factor in certain of the vomitings during pregnancy, there remains a class of cases in the great majority of which we cannot demonstrate conditions named in the texts as etiologic factors.

PATHOLOGY

The pathologic picture varies within wide limits, yet the liver is the seat of the most important changes. The milder cases of vomiting which come to accidental death present little more than cloudy swelling of the parenchymatous tissue. Yet nearly all the cases of vomiting which result fatally present structural changes in the liver ranging from the simple fatty forms to those characteristic of acute yellow atrophy. The most marked type presents degenerative changes which begin about the central vein of the lobule and gradually extend toward its periphery.

The serious vomitings of pregnancy have been classified clinically under many headings. The chronic and acute forms have been recognized for many years, the former as a slow and gradual development from the more severe type of morning sickness which rarely changes type until late in the disease, and the latter with acute onset and rapid progression soon characterized by extreme prostration and a fecal type of vomiting. Quite naturally attempts were very early made to establish a classification on etiologic grounds and the serious vomitings have been grouped accordingly as due to reflex-neurotic or toxicemic causes. The chronic forms mentioned above correspond usually to the reflex-neurotic group which essentially is nontoxic in type in contradistinction to the acute forms which are frankly toxicemic. Yet the whole question of clinical classification hinges largely on the pathology, which appears to countenance the clinical divisions, since patients dying from the neurotic-reflex nontoxic or chronic groupings present liver changes of the simpler types, whereas the liver changes are most marked in the cases of the toxicemic group. Yet the whole question is not so simple as would first appear, because deaths in the chronic groupings are comparatively rare and are even more infrequently investigated by careful necropsy. Moreover, patients dying of the toxicemic type of vomiting occasionally present only liver changes of comparatively slight forms which are in no way suggestive of the lesions of acute yellow atrophy so often encountered. So it is quite problematic whether the pathologic picture presented in the liver of those who die of any or all types of the serious vomitings represents various progressive stages of the same process.

The importance of the liver in the pathology of the disease was presented as early as 1879 by Matthews Duncan, but was lost sight of almost immediately until revived by the cases of Stone and Williams in 1901 and 1902. Many have turned their attention to study of the liver function, but thus far no one method has given assurance of accuracy.

It is a mark of wisdom of American teaching that abortion is resorted to early rather than late when the patient does not respond to the ordinary therapeutics. Yet this treatment, while safe, is undoubtedly unsatisfactory, in that, contrary to the opinion of Tarnier and

Budin, the disease tends to recur in subsequent pregnancies. It therefore follows that men who are interested in this problem nearly always have in charge patients who have aborted in the past but who are willing to endure even considerable risk of life to secure a living child.

DOCTRINE OF AMMONIA COEFFICIENT

Several investigators had studied the partitions of the urinary nitrogen in the toxemias of pregnancy without convincing conclusions prior to 1905, although Whitney's observations on a small series of eclampsia cases strongly suggested that an increase of the ammonia coefficient in that disease might be a protective measure. Folin's observations on thirty normal urines and their variations following changes of diet had not been recorded when Williams undertook the investigation of the urine in a series of vomitings of pregnancy. Williams found that there was a marked difference in the ammonia coefficient in the cases of the reflex-neurotic and the toxemic types, the former remaining at normal limits whereas the latter ascended to 32, 38.5 and 46 per cent., respectively, in three of his cases. After a careful review of the literature, he confessed his inability to determine the cause since there was an absolute lack of knowledge concerning the toxic material at fault and whether it was derived from mother or fetus. Whether it was merely a manifestation of an acid intoxication or the inability of the diseased liver to effect complete oxidation, future investigation might determine. Numerous investigations by other observers have confirmed his observation in part, some, as Underhill and Rand, concluding that the increase in the urinary ammonia nitrogen was indicative merely of an acidosis of starvation, while others have controverted the theory, stating that the toxemic type may exist without such a resulting condition. Since that time, we have learned much concerning the formation of ammonia. We recognize that it is influenced profoundly by the type of diet and by medication and by other factors, that it probably is not an index of the liver functions, but that the fact remains that it is increased in the condition of acidosis, and serves the purpose of saving alkali for the body.

ERRORS OF AMMONIA COEFFICIENT

My observations, begun shortly following Williams' investigations, have convinced me of the general truth of his work; namely, that the more serious vomitings are characterized by an increase of urinary ammonia, yet because of many factors influencing the coefficient it is better to state the ammonia nitrogen in terms of absolute amounts, since without this control the ammonia coefficient occasionally may be misleading. The coefficient is the proportion of the total urinary nitrogen that presents as ammonia. If the absolute amount of ammonia remains stationary, the coefficient will decrease with an increase of total nitrogen and will increase with the fall. This is clearly shown by Folin when presenting the variations seen in health. Under a diet giving 16 gm. of total urinary nitrogen, the ammonia weighed 0.7 gm., giving an ammonia coefficient of 4.3 per cent. When the patient was given a nitrogen-free diet only 3.6 gm. of total nitrogen appeared in the urine. The ammonia nitrogen weighed 0.42 gm. yet constituted 11.3 per cent. of the total nitrogen. That is to say that the ammonia coefficient rose from 4.3 to 11.3 per cent. in spite of an actual reduction

in the absolute amount of the ammonia, the change being accomplished largely by the fall of total nitrogen. Yet without all of these figures, the rise of the ammonia coefficient might be taken as an indication of a beginning acidosis. A further example of the occasional failure of the ammonia coefficient to express the true facts is shown by the accompanying chart.

If the total nitrogen remains stationary and the ammonia increases in amount, the ammonia coefficient increases, thus resembling the curve of the increase of ammonia by weight. Yet this condition is not frequently seen in the severe types of vomiting.

Because of the restriction of food, the total nitrogen in the urine comes largely from the breaking down of body tissues. Comparatively little nitrogenous tissue breaks down early in starvation since the loss in weight depends in large part on loss of fats, the fatty acids

The absolute amounts of ammonia are printed on the curve of the ammonia coefficient. Had it been charted, the curve would have given warning of the seriousness of the case one day before the rise in the ammonia coefficient did so. After the abortion the coefficient fell (because the total nitrogen had risen) to what was considered a safe margin. In reality, the ammonia had not fallen but had increased in amount from 1.51 gm. to 3.23 gm. without marked disturbance in the ammonia coefficient. The case is taken from literature.

being oxidized largely by the action of the glycogen stored in the liver. We should expect, therefore, variations in the partitions of the urinary nitrogen in fat and thin subjects, dependent in turn on the relative amounts of carbohydrates stored in the body suitable for oxidation of the resulting fatty acids. The character of the last food ingested is also important, since Voit has shown that in a dog the influence of the last meals persisted for the first six days of starvation.

ACIDOSIS IN NORMAL PREGNANCY

Realizing that urinary ammonia gives at best a poor record of the acidosis, I had Emge in my clinic undertake a series of investigations to determine the acidity

of the blood in normal pregnancy. His work, reported in 1916, and since then confirmed by others, shows that there commonly exists in normal pregnancy an acidosis, as shown by the tension of the carbon dioxide of the blood in the method of Van Slyke, yet that the blood readings of the majority of our vomiting series fell within the same range as cases considered clinically as normal. A smaller number of cases presented readings at the other end of the scale, reading as high normal, whether as a result of medication (alkalis) or not, we do not know. Our investigation of the total non-protein nitrogen and the urea nitrogen of the blood show normal limits for all cases.

URINARY AMMONIA IN NORMAL EARLY PREGNANCY

Some years ago, R. W. Webster and myself investigated the partition of the nitrogen in four normal patients, two or three months pregnant, who had not vomited and had only very slight and infrequent nausea. Two were nulliparas and two were multiparas, one of each pair was slight and the other somewhat stout. Both multiparas could be classed as neurotic. The diet was mixed and was calculated for 10 gm. of nitrogen for the two women weighing under 120 pounds and 14 gm. for the two women weighing more than 150 pounds. The urine was followed for three successive days, yet since they present the same range we will record only one. One case in the fifth month of pregnancy was selected for observation and followed from that time throughout, with daily study during the last thirty days. The diet in this case was not controlled. We also have as other controls a urinary investigation in a woman five months pregnant who was threatening abortion, and two observations on an early pregnancy complicated by a duodenal ulcer which had long caused vomiting.

RANGE OF URINARY AMMONIA IN SEVERE VOMITING OF PREGNANCY

From the foregoing it is evident that the case as presented by Williams stands or falls with the ammonia content of the fatal cases, or those aborted at the eleventh hour to avoid impending death. Personally, in more than forty examinations of cases which R. W. Webster and myself, or I myself, or my technician working with me, have made, I have never seen a

patient adjudged by clinical means as in danger of life with urinary ammonia of normal limits. The fact that high ammonia is occasionally seen in cases that do not give symptoms of marked toxicity in no way impairs the truth of the general statement, since the loss of fatty tissues, the glycogen content of the liver and muscles, the character of the food retained, the type of medication employed, all constitute factors that must be considered in any given case. We have found a

total nitrogen range from 3.6 gm. to 8 gm., and an ammonia variation between 1.8 and 3.1 gm. in twenty cases of the severe type of vomiting. Lower ammonia readings were found in a considerable number of patients who, although they stated that they had had constant vomiting before our study, did not vomit to any considerable extent while under our observation and treatment. One patient with a fairly severe, long protracted and stubborn type showed a rather low range of ammonia (about 1.5 gm.) and finally aborted two months after our first observations. One very severe case in which abortion was induced because of unfavorable symptoms presented 1.8 gm. of ammonia and 4.4 gm. of nitrogen just before the abortion. The history stated that she had been ill for more than two months and had retained no food for more than a week (the latter statement we consider somewhat doubtful). The urine contained much acetone and diacetic acid, a faint trace of albumin and many granular casts; leucin and tyrosin were found without effort made to concentrate the bulk. The toxic features of this case were further suggested in that, while the vomiting ceased after the abortion done under local and analgesic nitrous oxide-oxygen, death following an acute paralysis of the Landry type, complicated by Korsakoff's syndrome, occurred three weeks later.

URINARY AMMONIA IN STARVATION

The question now arises as to whether this increased ammonia is indicative merely of the acidosis of starvation as suggested by Underhill. No student of the metabolism in cases of pernicious vomiting can doubt for a moment that starvation enters largely into the picture, but I cannot see how any can believe that it is responsible for the entire change, since the ranges of ammonia seen in actual starvation are greatly exceeded by those encountered in the vomitings. The absolute amounts of ammonia nitrogen excreted in Bonninger and Mohrs' fasting woman Schenk ranged from 0.40 gm. on the second day to a maximum of 1.84 gm. on the seventh day of the fast. Benedict's subject L. gave similar findings, 0.41 gm. on the first day with a maximum of 1.94 gm. on the seventeenth day, an amount in excess of that of Beauté in Cathcart's research and of Brugsch on Succi. The maximum ammonia coefficient in Benedict's fasting case is 21.79 per cent.; in Williams' vomiting case, 46 per cent. The rapid fall in the ammonia in Benedict's subject after taking food is of the greatest interest (from 1.24 to 0.69 gm. on breaking a fast of thirty-one days). Yet these observations are made on individuals who are about on their feet. On the other hand, you quite commonly encounter ammonia nitrogen of more than 2.4 gm. in vomiting cases in which the patients have been in bed for days and who have retained some food by mouth to say nothing of glucose by blood or by rectum. Moreover, the total nitrogen often falls below that encountered in any record in starvation, excepting only Freund's observations of Succi which are not acceptable to later workers. It is unfortunate that no professional faster has been content to present for study while on a nitrogen-free diet, which would give another angle for comparison, much needed for complete controls.

So it appears as follows: There is an acidosis in pregnancy as evidenced by the reading of the carbon dioxide tension of the blood, yet the tension of the vomiting cases does not exceed that of normal cases in which there is no vomiting. The ammonia nitrogen of our normal pregnant controls ranges around 0.5 gm. In vomiting from ulcer in pregnancy it also ranges low, whereas in vomiting cases it exceeds that noted in any series of actual fasting.

Finally, therefore, it appears that the crux of the question lies in the point as to whether in a vomiting case presenting ammonia nitrogen in excess of that seen after many days of actual fasting there is a return to normal limits with the cure of the vomiting and the preservation of pregnancy. Williams' observations show that it does so after abortion. My observations indicate that it does so return after proper treatment and with the preservation of pregnancy, as evinced by the typical case summarized in Table 5.

The simpler nausea and vomiting cases in early pregnancy correspond in large part to the clinical picture of the so-called neuroses of the stomach. We may encounter all types. The most common one suggests the hyperacidity group in that the vomiting ordinarily occurs at the height of digestion. Almost invariably they are relieved temporarily by taking food. The mouth is acid to litmus. The eructations are acid. Constipation is the rule, almost without exception.

CYCLES OF VOMITING

There are usually three periods in which the nausea is most marked. The most common period is the early

morning; the second is late in the afternoon, and the third is shortly before noon. At first the patient conforms to one type alone, but later she may vomit at all three periods, and subsequently after meals as well. Gastric analysis shows increase of acids. Motor neuroses are common. The patient is worse in the morning because of the long fast during the night, although the stomach usually empties itself in a normal manner during this interval, so that the morning vomitus is chiefly acid mucus. Yet occasionally the pylorus becomes so irritated by the acid secretions during the night fast as to close in spasms with retention of larger amounts of the offending fluids, which are vomited shortly after arising. Vomiting may also occur immediately after taking food. The nausea in the late after-

noon is common in patients who eat a scanty pickup luncheon, often most badly selected. The type of patient whose usual breakfast is coffee and rolls gives a wave of nausea about eleven in the morning.

Yet all cases do not belong to this category and the subacid type is not uncommon. Indeed, the most troublesome cases are often in this group, which often present as primary and without an acid mouth or increased stomach acidity. Yet it would appear that cases which sometimes begin as hyperacid types may change to the subacid type after long standing.

TREATMENT

The successful treatment demands a most rigid attention to details and no item is too slight to merit attention. I cannot urge too strongly a careful study of the gastric secretions and titration of all vomitus. Nothing seems more ridiculous than to pass all patients

by with the statement that a pregnant woman must expect to vomit.

It follows without question that we should search with the greatest care for any of the conditions which texts mention as causal factors. Posterior displacements should be corrected and held up by pessaries, although I have never seen relief follow such measures alone. The care of the bowels is exceedingly important and there is much opportunity for skill in the treatment of the troublesome constipation, since cathartics are not usually well borne. We should restrict medication by mouth to the few drugs later mentioned. There is, of course, no need of emphasizing the necessity of proper hygiene, well constructed clothing, proper ventilation and the avoidance of excitement.

VOMITING AS A NERVOUS HABIT

I am of the firm belief that the formation of a nervous habit of vomiting accounts for the great majority of the cases of moderate severity which develop from morning sickness, since there is nothing more easy to acquire than the habit of vomiting in the presence of nausea. We should seek, therefore, to break this habit and to treat, at the same time, the underlying cause of hyperacidity or subacidity, in part by medicine but chiefly by a type of food which, while easy to digest, is difficult to vomit. We must not expect to secure good results unless there is absolute rest and quiet. Hospital care is most advisable and a stay of more than ten days is rarely necessary. It is most difficult to treat successfully a patient surrounded by her family and with the weight of household cares even though she is in bed and under a nurse's care. A good start is necessary and it is seldom obtained while the patient is at home.

The patient is put to bed. All food and drink by mouth is stopped until there has been no vomiting for twenty-four hours. The bowels are kept open by a daily high colonic flushing. The patient is put under the influence of large doses of bromid given by rectum, beginning with 40 to 60 grains every four hours. A solution of glucose and soda is given by rectum. We have long since found that these are best given in doses of 8 to 10 ounces at fixed intervals since the drip method soon causes irritation. It is exceedingly important to assure the patient that she will retain the first meal given, to explain the plan of treatment, and to warn her against vomiting when she is nauseated. It should be explained that the vomiting habit is very easy to form, but very difficult to break.

The type of food varies within limits yet at no time should it include fruits or sweets. It is necessary that it should be given as dry as possible and the meal should be of the solid type. The hyperacidity group responds quickly to a diet of proteins, limited fats and restricted carbohydrates. The glucose by rectum supplies the deficiency of the carbohydrates, while the sodium bicarbonate is used to neutralize the acidosis. I have found nothing as useful as the diet of meats, twice toasted bread with butter, and a small amount of milk and cream, to be taken as a ration, all or none. A patient should begin with at least four such meals a day. Fluids by mouth are withheld for many days and until the diet has been extended to include vegetables. Then we may give alternatively solid and fluid meals—in small amounts and at frequent intervals.

There are many objections to this type of diet which quickly palls because of the restricted choice of meats,

since broiled steak, roast beef and slightly cooked scraped beef must constitute the standby for several days. Yet a patient will usually take it until the most distressing time has passed, when other meats may be added. The diet for the subacid type is far more difficult and should be more mixed with fewer meats. The bromids are now gradually reduced and soda and magnesium are given in capsules by mouth during the period of digestion. With the exception of occasional pills, given with meals, I have found no other drug of the slightest value except ipecac.

It seems most remarkable to me that so little attention has been paid to the diet. Nearly all texts advise milk and other fluids which are not only easy to vomit but which react occasionally in a somewhat toxic manner, a point recently emphasized by Tweedy of the Rotunda. The chief qualification is that the food shall be solid, dry and in small amounts. Years ago I was impressed by the manner in which a steward on an Atlantic liner treated seasickness in a fellow passenger. For the first meal he gave a chop. "It will stay down," he said, "one vomits liquids easily."

Patients invariably suffer from a parched mouth and demand acid drinks. They clamor for drinks of lemon and orange, yet some very sharp mouth wash helps out wonderfully. The sweeter type of mouth wash usually nauseates. I cannot emphasize too strongly the necessity for the most careful observation of details. A nurse may give a low enema instead of a colonic flushing. Some one invariably brings grapefruit which promptly causes vomiting. The patient is so thirsty that she will drink the water from the finger bowl or reject the solid food and take only the milk and cream. One must obtain the patient's confidence. Yet this treatment rarely fails when properly controlled in chronic cases. It should not be attempted with the fulminating type of case nor with one with black vomit or other signs of toxemia. These should be aborted without delay and very often one is too late. Gastric lavage is seldom helpful as an adjuvant to the treatment.

The question naturally arises as to what constitutes a safe limit of urinary ammonia. We cannot answer. Yet it seems rational to treat the acidosis as well as the actual vomiting when the ammonia runs very high and to induce abortion in the presence of unfavorable symptoms. We should constantly keep in mind the resemblance to the ammonia excretion in diabetes. Ringer's solution gives excellent results given alternately with the glucose-soda solution since it does more to quench the thirst and is most valuable in the treatment. I have had no results with injections of normal pregnant serum, as advocated by Freund and others, in any case which did not respond to our treatment. There is some doubt as to the basis for the injection of normal pregnant serum. Many claim that it depends chiefly on the blood content of calcium. Epinephrin has not proved of value in my hands nor has corpus luteum. With an acidosis not influenced by the treatment and with a continuance of severe symptoms, we should resort to abortion. More latitude may be given a case of equal clinical severity that does not present marked acidosis. We should aim in the beginning to keep on the safe side. To this extent, I believe we should rely on the study of urinary ammonia.

It may be urged that ammonia determinations are complicated procedures which in consequence must be done by a trained chemist. Yet the newer methods of Folin and Van Slyke have done much to solve this

problem. Hospital interns are now taught them as a routine and even if they are not so taught a case may be controlled by titrations with formaldehyd solution, which are sufficiently accurate for clinical purposes and easy to do.

THE METHOD OF ABORTION

The method of abortion is entitled to the most serious consideration if that treatment is finally chosen, since there is little doubt that it occasionally causes death in very serious cases, partially because of the shock following ill chosen methods but largely because of the drug used for anesthesia. No one who has followed the work of Whipple, Graham and others on chloroform poisonings can conclude other than that chloroform has been responsible for many of the lesions in many of the cases of the acute yellow atrophy type, not necessarily as a primary cause but certainly as contributory. Chloroform is absolutely contraindicated in any case in which it would appear that the liver has used up most of its glycogen. It will certainly cause serious damage to a liver already the seat of a pathologic process. Ether is objectionable, partially because of the acidosis which its use entails but chiefly because it adds to the vomiting. Local anesthesia suffices for nearly all necessary procedures. It may be augmented by nitrous oxid and oxygen in analgesic doses, never given to the anesthetic degree. The greatest care should be taken to keep the patient in the twilight stage and not to permit loss of consciousness. The method of procedure is equally important and deserves the most careful consideration since the patient may have advanced so far in pregnancy that you may not remove the fetus through the dilatation obtained by Hegar catheters. Vaginal hysterotomy may then be indicated, especially if the cervix is long and high. Yet we must keep in mind the possibility of infection since the resistance of the patient is usually so low. Bags may be used, yet they, like packing, often augment the symptoms of many cases. Do everything possible to avoid catheterization, since bladder infection and pyelitis may be the source of an infection responsible for the severest type of neuritis.

Few conditions, therefore, may offer more opportunity for proper treatment. Yet, so long as both the medical profession and the laity alike believe that a pregnant woman must expect to endure nausea and vomiting, we may expect to give treatment in serious cases.

ABSTRACT OF DISCUSSION

DR. ALFRED BAKER SPALDING, San Francisco: It is hard to discuss this paper because we know so little about the etiology and we have so many personal opinions about treatment. We know that every woman who becomes pregnant is more or less toxic. We know that about 60 per cent. start to vomit from reverse peristalsis, beginning with constipation and ending in vomiting. Two tenths of 1 per cent. will have serious vomiting. Occasionally a woman dies. I have seen one death. It is unusual to see a woman die from this condition. Why do these women vomit, and why do they become seriously ill, and why do they die? All we know in regard to the pregnancy is that there is a foreign element developing in the ovum against which the body reacts producing symptoms in some persons but not in others. Autosuggestion has an influence, for in some cases even the husband starts to vomit. I do not believe all women are in the same condition for pregnancy. Some women are well and strong, and I believe much in the rôle of focal infections in the pregnant woman. I am convinced

that the teeth form the basis of many of the abnormalities seen in pregnancy, particularly in regard to vomiting and in regard to the high blood pressure and other toxic conditions of later pregnancy. In the record of fatal cases reported by J. Whitridge Williams some years ago I saw that one patient just before death had had a severe tonsillitis. In another case the patient was found at necropsy to have had an ulcer of the vagina. A patient of my own, who in three pregnancies had vomited excessively, has had severe gonorrheal inflammation because her husband would not be cured. An interesting point in this case is that with the cautery I have cleaned up the cervix so that it looks like the cervix of a woman who never had a child. It is now about the fifth month of pregnancy and the woman has not vomited once. This leads me to believe that some of the cases are due to focal infection. As to the urinary nitrogen, in one case during the period of treatment from July 22 to August 12, the total amount of urine was a little under the normal until we aborted the patient. The nitrogen started at 6 gm. but dropped until the day before we aborted her to 2 gm. An interesting fact in this case was that the nitrogen coefficient increased from 10 to 37 per cent., while the patient clinically was very sick. This brings out Williams' idea and we based our treatment on the report of his cases. There is great need for some functional test of the liver. Unfortunately, the liver may be largely destroyed and yet functionate. In this particular case we tried the test for urobilin and urobilinogen. Two examinations were made. One of these was made early and showed only slightly increased urobilin in the urine. The day before we aborted her urobilin was present in the urine to the thirteenth dilution.

DR. ELMORA C. FOLKMAR, Washington, D. C.: I wish to call attention to the fact that we may sometimes make use of other means than drugs and diet or treatment by abortion to relieve the patient of these distressing symptoms. Within the past year I have had six cases of nausea of pregnancy. Three of these cases had reached the point at which I felt it was wise to place them in a hospital and have laboratory tests made, but before doing so I tried the use of body radiation with actinic rays, making approximately ten treatments on ten successive days. In each case the vomiting ceased within the ten days and the patient felt perfectly well. Just how this was brought about we did not know. The study of the effect of light on metabolism is not fully known. We do know that the application of the actinic rays in some way brought metabolism to nearly a normal condition. We know that the rays increase oxidation.

DR. FRANK W. LYNCH, San Francisco: I should like to emphasize a few points concerning the use of ammonia in selecting cases for medical treatment. While we do not believe for a moment that the urinary ammonia is the best indication of the extent of the acidosis, we have found it to be a better clinical guide than the carbon dioxide tension of the blood. We have not yet studied a series of cases controlled by the study of alveolar air. The ammonia nitrogen in the urine does not appear to be so quickly influenced by treatment with soda bicarbonate as the carbon dioxide blood tension, and nearly all cases presenting for treatment have had large doses of soda. Many of our cases which have had soda treatment have had high normal (60) carbon dioxide tension and yet their urinary ammonia has been greatly in excess of that deemed the highest normal limit. The carbon dioxide blood tension quite naturally varies, depending on the condition of the body cells and the fluids which come from around them to form blood plasma. If the acidosis as expressed by the urinary ammonia appears to be controlled, we will persist longer in our treatment in spite of the vomiting than if the ammonia ran extremely high with equally bad clinical symptoms. Yet under no circumstances would we continue medical treatment if the patient had the so-called black vomit. There are no cases accepted by students of metabolism in which the total urinary nitrogen in actual fasting has fallen below 3 gm. The case of Succi investigated by the Freundt nearly twenty years ago in Vienna is not now accepted since the methods then used were not possibly so accurate as at the present. Yet in many of

our cases as in that of Dr. Spalding we have found lower total urinary nitrogen than any observation in actual fasting. We are somewhat skeptic of these observations. Yet it appears that we should not expect to have as much breakdown of protein tissue when we use *tis-ne* sparing food, which nearly all vomiting cases retain by rectum, as in cases of actual fasting. We do not know, however, to what extent the condition causing vomiting may break down protein material, whether more than in actual fasting, as seems likely, or not. It is unfortunate that we have no good records as controls of partial fastings where glucose or some other carbohydrate was used for food since all fasters appear to object to such form of diet, preferring actual fasting. We no longer give glucose into the vein since we find that patients absorb it very well through the bowel.

INFECTIONS OF WOUNDS OF WAR

WITH SPECIAL REFERENCE TO GAS GANGRENE

ROSWELL T. PETTIT, M.D.

Captain, M. C., U. S. Army
OTTAWA, ILL.

The work which forms the basis of this paper was done in the transportable laboratory assigned to evacuation hospital No. 8 during the St. Mihiel and Argonne-Meuse operations. An effort was made to obtain information of a clinical character, such as that relating to the time between the injury to the patient and the operation; exposure to wet and cold; influence of shock and exsanguination; character of wounds—whether produced by shell fragments or rifle bullets; removal or retention of foreign bodies; impairment of local circulation; involvement of bone; character of the soil over which the fighting occurred, and, lastly, the nature and the influence of operative interference.

Along bacteriologic lines, a special effort was made to secure the more important anaerobes, such as *B. welchii*, *Vibrio septique*, *B. oedematiens* and *B. sporogènes*. The hemolytic and nonhemolytic varieties of streptococci were studied in cases in which gangrene had developed and in those in which it developed later, and also in the cases showing no evidence of gas gangrene at any time. Familiarity with the work done in evacuation hospitals teaches that much of this information cannot be collected during periods of great activity; the rush is so great that it is impracticable to take more than a few condensed notes.

During the month of October it frequently happened that more than 200 patients were operated on under a general anesthetic within twenty-four hours. On a number of occasions, with eighteen tables in the operating theater, manned by twelve surgical teams operating in two shifts (day and night), more than 150 patients at one time awaited operation in the reception ward. Clinical data could not well be gathered, and similar difficulties were encountered in securing bacteriologic data. In a number of instances, fifty cultural examinations were made within twenty-four hours. In the majority of instances, the isolation and study of pure cultures of the various bacteria was not attempted. All cultures were made on four types of mediums under aerobic and anaerobic conditions. Examinations for morphology and motility were made in each case; and, for the purpose intended, the results are fairly exact, determining the presence of hemolytic streptococci and *B. welchii*. Other anaerobes were classified together as "unidentified anaerobes."

Between Sept. 10 and Nov. 13, 1918, 4,471 surgical cases were admitted to the hospital. Of this number 4,377 patients received wounds in action, of which 2,993 were single and 1,387 multiple. The total number of wounds in all cases was 6,207 and 4,683 were treated surgically. They were distributed as shown in Table 1.

In 206 of the 4,377 cases in which wounds were received in action, amputation was necessary, the determining factors being (a) severity of injury, (b) streptococcus infection, or (c) gas gangrene. Table 2 shows that most amputations of a minor nature were due to the severity of injury. Amputation of a limb was most frequently made necessary by gas gangrene.

In the period from Sept. 10 to Nov. 13, 1918, there were 363 deaths in the hospital. The more important causes are given in Table 3. Gas gangrene was a most important cause of death. Of 4,377 patients who were wounded in action, 221 had gangrene (5 per cent.). This is a high incidence, but it is to be noted that this hospital received only those seriously wounded, and

TABLE 3.—CAUSE OF DEATH IN THREE HUNDRED AND SIXTY-THREE CASES FROM SEPT. 16 TO NOV. 13, 1918

most of the cases of gangrene were received very late. Of 157 cases of gangrene in which a definite record could be obtained, there was well developed gas gangrene in 141 on admission to the hospital (90 per cent.). In sixteen cases gas gangrene developed after the patients had been operated on. A sharp contrast is noted between the incidence of gas gangrene devel-

oping after operation (sixteen out of 157 cases) and that of gangrene well developed on admission (141 out of 157 cases).

The average length of time between injury and operation in 162 cases of gangrene was 41.8 hours. In 349 similar severely wounded, nontransportable cases, in which gas gangrene did not develop, the average length of time between injury and operation was 24.67 hours. These figures reveal the importance of early operation in preventing gas gangrene.

Dividing the 162 patients with gangrene into groups, with the division based on the time interval between injury and operation, the number who fall in each group can be determined. The same can be done with the 349 similar cases not showing gas gangrene (Table 4). From these figures the percentage inci-

dence of gangrene in each group can be determined; for example, of forty-six cases received between 48 and 60 hours after injury, twenty-three (or 50 per cent.) had gangrene. These figures are represented graphically in the accompanying chart. The obvious deduction from these figures is that early surgical interference is one of the most important factors in preventing the development of gas gangrene.

In the majority of instances, the heavily muscled parts of the body are most frequently involved. One third of the cases in this series occurred in the leg. The distribution is indicated in Table 5.

The total number of wounds treated surgically was 4,863. The incidence of gangrene is shown in Table 6. The highest incidence is seen to be in wounds of the shoulder and of the leg and, in the order named, in the arm, buttocks and thigh.

There was impaired circulation in 174 cases in which a record concerning this point could be obtained from the operation notes. Of these cases, gas gangrene developed in thirty. In this group there was extensive destruction of important blood vessels in 17.8 per cent. Fractures of the large bones occurred in seventy-two of the 174 cases.

As transportable patients were evacuated within forty-eight hours after operation, bacteriologic examinations were restricted to cases in which the patient could not be removed. They were principally those of injuries of the head, chest and abdomen, and fractures of the long bones; also those of gangrene. Cases of this character were under observation in the hospital

for from four days to two weeks. Bacteriologic examinations were made as shown in Table 7.

PROCEDURES EMPLOYED

Cotton swabs on wire rods in small test tubes were sterilized by dry heat at 170 C. for one hour. They were prepared by the laboratory and placed in the operating room and wards. Six assistants were assigned to the day and night shift in the operating room (three to each shift). Their duties were to write the clinical records of the operations, take the cultures, unless the surgeons took them themselves, and to make out the clinical portion of the bacteriologic record chart.

These swabs in their tubes were sent to the laboratory and planted in liver peptone water. At the end of from six to eight hours a microscopic examination was made of a fresh specimen for motility, and of a stained specimen for chains of cocci and for bacilli. Subcultures, in all instances, were made in litmus milk, Veillon agar and on blood agar slants. The cultures were examined at the end of from eighteen to twenty-four hours, as follows:

Liver peptone water.—Microscopic examination of all cultures negative on six-hour examination, and notation made of the amount and character of cloudiness, sediment, pellicle and odor.

Blood agar.—Examination to determine the presence or absence of hemolytic pinpoint colonies, and the character and extent of surface growth and odor.

Litmus milk.—Examination to determine acidity and gas production.

Veillon agar.—Examination to determine the size, number and character of colonies (naked eye, hand lens and microscopic 200 X), and the gas production.

All mediums except blood agar plates and slants were boiled and cooled immediately before use, and calcium sulphid was added to the milk and the liver peptone water just before they were employed, and to the Veillon agar immediately after it had cooled.

In some instances more detailed examinations of pure cultures were made, but the majority of examinations were made as outlined above.

RESULTS OF THE EXAMINATIONS

Of 890 wounds examined bacteriologically, 478, or 53 per cent., were found to contain anaerobic bacilli.

Of these 478 wounds, 321, or 67 per cent., at no time showed clinical evidence of gas infection.

Of the remainder—the gas gangrene cases—in sixteen, or 3 per cent., gas gangrene developed after operation (debridement), while in 141 cases, or 29 per cent., gas gangrene was clinically evident at the time the bacteriologic examination was made.

It is thus seen that, in my experience at least, more than two thirds of the wounds contaminated with anaerobes did not develop gangrene. All of these cases were under observation at least five days, and some of them more than two weeks.

In only a very small percentage of cases did gangrene develop after operation. One hundred and fifty-seven cases of gas gangrene were examined bacteriologically. In eighteen of these cases the cultures were taken at a distance from the wound, from incisions above the wound and from the amputation stump. In 139 cases in which cultures were taken directly from the wounds, the relation of *B. welchii* to the other anaerobes in cases of gas gangrene clinically determined was as follows:

B. welchii was the only anaerobe found in twenty cases, or 14 per cent.

B. welchii was absent, but other anaerobes were found on culture in thirty cases, or 21 per cent.

B. welchii and other anaerobes were found together in eighty-nine cases, or 65 per cent. A combination of *B. welchii* with other anaerobes was thus found in two thirds of the cases examined.

A statistical study of the relative frequency of the streptococcus, both hemolytic and nonhemolytic, was made in cases free from gangrene, and in cases in which gas gangrene was clinically evident.

Of all the wounds examined (890), chain forming cocci were found in 219, or 24.6 per cent.

One third of these (seventy-three strains) were of the hemolytic variety, and two thirds (146 strains) were of the nonhemolytic varieties.

In 139 cases of clinically determined gangrene, streptococci (both hemolytic and nonhemolytic varieties) were found, together with anaerobes, in forty-four cases, or 31.6 per cent.

In fourteen cases out of these forty-four, or in 32 per cent., the streptococci were of the hemolytic variety.

In 321 cases without gangrene, streptococci and anaerobes were found together in ninety-seven cases, or 30 per cent. In thirty of these ninety-seven cases, or in 31 per cent., the streptococci found together with anaerobes were of the hemolytic variety.

These results show that the streptococcus—both hemolytic and nonhemolytic—was no more frequent in gangrenous wounds than in nongangrenous wounds.

CONCLUSIONS

From the results the following deductions are warranted:

1. The most important factor in dealing with gangrene is early operation. This is a matter of transportation.

2. A majority of wounds are contaminated with anaerobic bacteria without the development of gas gangrene.

3. Many cases of gangrene are due to anaerobes other than *B. welchii*.

4. In most cases of gangrene, *B. welchii* is associated with other anaerobic bacteria.

5. The streptococcus (both hemolytic and nonhemolytic) is apparently of little importance in the production of gangrene.

Incidence of gas gangrene in relation to time interval between injury and operation. Total number of patients with gangrene, 162; patients without gangrene, 349. This chart demonstrates that after eighteen hours the percentage incidence of gas gangrene in the severely wounded and nontransportable patients increases markedly.

Public Health Nursing.—To those who have followed the development of public health work in this country it becomes more and more evident that much of the progress is due to the introduction of public health nursing as an integral part of public health administration. Unfortunately, a very large number of communities in the United States are still without a public health nursing service. It seems not to be realized that such a service constitutes a well-paying investment. Yet nothing has been more clearly demonstrated. Progressive health administrators who have had experience with public health nursing are unanimous in praise of the results obtained. More than ever before there is great need for additional well-trained workers in this field. It is to be hoped the time is not far distant when every community throughout the United States will enjoy the benefits of a system of public health nursing, for experience has demonstrated that this is an invaluable measure for bringing the work of the health authorities to the people.—*Public Health Reports*, June 6, 1919.

Clinical Notes, Suggestions, and New Instruments

METHOD OF REMOVING VARICOSE VEINS

JOHN A. TAMMISIEV, M.D., HOWELL, NEB.

Varicose veins are the cause of the heaviest loss of *Al* men that we encounter in the army. I was attached to the British Expeditionary Forces and was stationed in their Base Hospital No. 25 at Hardelot, France. It was at this hospital that all the "clean" surgery for the Boulogne area was done. In the beginning of the war a soldier who would report sick with varicose veins was usually sent to the base and later transferred to England for operation. As we all know, those poor men had gone through the worst of the war and were eager to keep out of all that they could in the future. It therefore became the duties of the medical officers to find a way to shorten every man's stay in the hospital.

These varicose vein cases were the first that any material speed was shown on. We devised a wire, preferably of silver, such as was used to wire bones, and on one end we put the base of an ordinary 0.303 rifle cartridge. We first filed the sides off and then bored the cap off and ran our silver through the hole and secured it with solder. This wire had to be quite pliable, but not too much so. The other end we beaded over a Bunsen burner. The wire in all was 40 inches long. We would put a tourniquet on the affected thigh and pick up the internal or external saphenous as the case happened to be, and then would make incision over it about 1 inch long, pick up the vein with hemostats, and tie off the lower end of it (distal end). Then we would pick

Wire with one end (A) beaded and the other (B) fitted with base of cartridge.

up the vein in the thigh by the same incision and tie off the upper end (proximal end). To open the vein up well we applied the hemostats to the edges and held them open while we inserted our wire. We then gently pushed the wire up and followed its course with our hand on the leg. This was usually done from the bottom, as in the pulling up on the wire we would take all the minor tributaries as well as the main vein. When the bead appeared at the higher incision we would grasp it well and have an assistant hold the foot firmly, and pull hard until our wire was entirely out and then we would have the vein gathered up on the wire in its entirety.

Very little if any hemorrhage resulted. We then put a stitch in each incision and an alcohol dressing over it. When our patients awoke they would be moving their legs around and would be greatly disappointed to find that they had no large bandages, no pain, and really no reason for asking to get to "Blighty." These patients were usually sent back to the lines in from ten to fourteen days.

A SIMPLE AND EASY METHOD OF BLOOD TRANSFUSION

ADDISON G. BRENIZER, M.D., CHARLOTTE, N. C.

I have taken my idea of the main piece of my apparatus for blood transfusion from a 10 c.c. ampule, containing sodium citrate in salt solution, issued with a transfusion set to the American Expeditionary Forces in France.

This ampule I have enlarged fifty times, bringing it up to a capacity of 500 c.c. Such an ampule I found commonly used in France for preserving and administering prepared sterile salt solution. I have modified this ampule somewhat, and have added two rubber tubes about 6 inches long, with a glass mouth-piece in one tube and a needle in the other. The apparatus is then complete.

The ampule is made of thick glass, and both ends are drawn out into tubes. One end is left straight and the other

is bent into a U curve. The extreme ends are flared slightly, and half an inch from the ends are apparently constricted (Fig. 1 A), or the straight lower end may be bent into a right angle curve or even tapered at the extreme end.

One of the rubber tubes is fitted with a short glass tube, blown out in the middle portion to hold a bit of sterile cotton. This serves as a mouth-piece (Fig. 1 B).

Fig. 1.—A, the 500 c.c. ampule containing from 2 to 3.5 gm. of sodium citrate in 50 c.c. of salt solution. The upper end is curved; the lower end is straight; both ends are stoppered with small rubber stoppers, tied in place. B, glass mouth-piece filled with sterile cotton in the bulbous portion and fitted into a short piece of rubber tubing. C, a short needle of large caliber fitted into a short rubber tube and tied fast.

The other rubber tube is fitted with a short needle of large caliber. The needle is tied in the tube with linen, and a wire is kept in it (Fig. 1 C).

Thus equipped, 50 c.c. of salt solution with from 2 to 3.5 gm. of sodium citrate in solution are sucked up into the ampule and the ends stoppered with small rubber corks, tied in (Fig. 1 A).

The ampule, along with the rubber tubes with glass mouth-piece and needle, respectively, are rolled in a cloth and sterilized in a constant pressure autoclave, or the different parts of the apparatus, including the salt solution and citrate,

Fig. 2. The parts A, B, and C assembled and ready for use. The citrate is let down to meet the blood. With the end B in the mouth and the end C in the vein, there is ample stretch between the two fixed points for shaking the ampule.

may all be simply boiled at the time of the operation, if time is not a factor and it is not desired to keep the apparatus ready sterile on hand or if an autoclave is not available. By hanging the ampule by its bent upper end on a bandage around the neck, the operator will be given free use of both hands.

The lower straight or even curved lower end is unstoppered, the rubber with needle fitted on and, with the free use of both hands, the donor's vein is needed. The blood begins to flow into the ampule on removing the stopper at the upper end, and may be markedly hastened by putting on the tube with mouth-piece and sucking. As the blood runs into the ampule, it is shaken with the citrate. When filled, the rubber tube at the bottom is pinched and the needle withdrawn from the vein (Fig. 2).

If the rubber tube is clamped at the top, opposite the needle tube, no blood will run out the needle, and the whole apparatus may be left suspended on the bandage around the neck of the operator, thus allowing free use of the hands again to needle the vein of the recipient.

The recipient's vein is needed, the clamp removed from the tube at the top, and the blood is allowed to begin to run into the vein of the recipient. The flow is hastened by blowing through the tube at the upper end. The rate of flow may be controlled by blowing or sucking on the mouth-piece. Any droplet infection or infection by saliva is prevented by the intermediary of a little sterile cotton stuffed into the amputated middle portion of the mouth-piece. When the ampule is emptied, the lower rubber tube is pinched and the needle withdrawn from the recipient's vein.

The recipient's vein may be needed subcutaneously or when it is collapsed, cut down on and needed; or, finally, the vein may be cut down on, incised, held wide open with two metal crochet needles, and the end of the ampule itself inserted and tied in. (This is the only phase or step of the operation in which an assistant is needed.)

The donor's vein should be needed against the blood stream, that is, toward the hand, and the recipient's vein in the direction of the blood stream, that is, toward the head.

The above-described manipulation can be done very quickly; in fact, so quickly that the ampule may be used paraffined or paraffined and washed over with citrate for whole blood. So used, the lower end is not only bent in a right angle curve, but is also tapered. The recipient's vein is then prepared for the reception of the ampule before needling the donor's vein.

609 North College Street.

A SIMPLE AND EFFICIENT METHOD OF COATING BLOOD TRANSFUSION TUBES WITH PARAFFIN

B. H. ALTON, M.D., WORCESTER, MASS.

During the past two years the citrate method of giving blood transfusions has been coming more and more into general use. Many surgeons who formerly employed the paraffin-coated tubes for transfusion have given up this method for the citrated blood.

The principal objection to the use of the paraffin-coated tube is the difficulty of obtaining a thin, even coating of paraffin. Coating tubes with melted paraffin is a long, tedious process, and good results are obtained only in the hands of those who are experienced in the method.

The advantages of the method I am about to describe are simplicity, rapidity, and the assurance of always obtaining a thin even coating of paraffin.

METHOD

The sterilized tubes are rinsed with a small amount of alcohol followed by a small amount of ether. About 1 ounce of a paraffin ether solution (paraffin, 1 part, 53 C. melting point, and 80 parts of ether) is poured into the tube.

The tube is shaken and rolled so that the solution bathes the entire inner surface. A small amount is allowed to pass through the cannula to insure a coating of the walls of its lumen. The remaining solution is quickly emptied through the top of the tube. The ether which remains on the surface quickly evaporates, leaving a thin, even coating of paraffin.

A rubber cork should be used with this method. It is prepared by pouring some paraffin ether solution over it and the ether is allowed to evaporate. The cork and tube are now wrapped in a sterile towel.

I have found that a tube coated by this method gives better results if it is not used for several hours after it has been prepared, as it allows a more complete drying of the paraffin.

The foregoing procedure is carried out under aseptic conditions. The paraffin used in the solution should be sterilized in an autoclave before being mixed with the ether.

I have used this method for the past two years in the British casualty clearing stations in France, and I have found it as satisfactory as paraffin applied by heat.

72 Pearl Street.

ANOTHER DIAGRAM FOR BLOOD GROUPING

M. W. LYON, JR., M.D., SOUTH BEND, IND.

Several diagrams have been published¹ showing the interrelations of the human isohemagglutination groups, and the manner of determining the group to which any person belongs by the use of serum obtained from persons of Groups II and III. By using both cells and serum of a person of Group II (or III) and those of an unknown person it is nearly as easy to determine the group to which the unknown person belongs as it is with serum of known II and III groups. While this fact has been long appreciated, so far as I am aware it has never been expressed diagrammatically. The diagram herewith is an attempt to do so.

In case the determination is to be made with a known III person, III should be substituted for II in the diagram, and II for III.

Diagram indicating the blood group of an unknown person, X, by interagglutination of X's serum and cells with those of an individual of known Group II, + indicates agglutination of cells; -, absence of agglutination. The possible combinations are indicated by connecting lines and the blood group of X by the Roman numerals inserted in the connecting lines.

As about half of all persons fall into either Group II or Group III, it is obvious that about half of all persons interested in blood grouping carry with them several hundred cubic centimeters of essential reagents for determining the blood groups of unknown persons.

¹ Sanford, A. H. Iso-Agglutination Groups, J. A. M. A. 67:808, 809 (Sept. 1) 1916; A Modification of the Moss Method of Determining Isohemagglutination Groups, *ibid.* 70:1221 (April 27) 1918.

Influenza Among Indians. In *Public Health Reports* of May 9, 1919, there appeared data furnished by the Office of Indian affairs in regard to the prevalence of influenza among the Indians. The mortality rates show that the epidemic was extremely severe among the American Indians. During the six months' period from Oct. 1, 1918, to March 31, 1919, over 2 per cent. of the Indian population died of influenza. The mortality among Indians in the mountain states, especially in Colorado, Utah and New Mexico, was very high. For the Indian population as a whole, the annual mortality rate from influenza alone during the six months' period was 41.2 per thousand, which is far above that for the general population—roughly about four times as high as that for the larger cities in the United States during the same epidemic period. It was pointed out by the Office of Indian Affairs that a second epidemic invasion occurred in certain localities after April 1, 1919, but the statistics of this second epidemic were not yet available.

MEDICAL EDUCATION IN THE UNITED STATES

ANNUAL PRESENTATION OF EDUCATIONAL DATA FOR 1919 BY THE COUNCIL ON MEDICAL EDUCATION

The tabulated statistics herewith presented are for the year ending June 30, 1919, and are based on reports received from the medical colleges or from other reliable sources. We take pleasure in acknowledging here the courtesy and cooperation of the officers of the colleges who have made the compilation of these complete statistics possible.

STATISTICS OF COLLEGES

Table 1, on pages 500-502, gives the colleges in session during 1918-1919; the population of the city; the rating given to the college in the latest classification of the Council on Medical Education; the number of students, men and women, registered during the year; the number of 1919 graduates, men and women; the number of graduates holding collegiate degrees; the number of teachers for each college; the number of weeks of actual work in the college year; the total fees for each year, the executive officer of the college, and the dates of beginning and ending of the next session. The figures in heavy-faced type show the totals by states. Beginning on page 523 are given essential facts concerning all medical colleges arranged by states.

HOME STATES OF MEDICAL STUDENTS

Table 2, on pages 504, 505, shows from what state the students came who were in attendance at each medical college during the session of 1918-1919. The influence of the proximity of the medical school is seen in the fact that states having medical colleges contribute more students in proportion to the population than those which have no colleges. This is shown by the dark zone of figures running diagonally down the page. A comparison of this table with the large tables based on state board examinations,¹ which show the distribution of the alumni of each college, is interesting. The college that has widely distributed alumni usually has a student body from an equally large number of states.

The state furnishing the largest number of students this year was New York with 2,003. Pennsylvania contributed 1,001 and Illinois 931. The next states, in the order of the number of students contributed, are: Massachusetts, 667; Ohio, 653; California, 523; Missouri, 469, and Texas, 428. Four states had less than 10 each, these being Arizona, 8; New Mexico, 7; Nevada, 6, and Wyoming, 8. There were 105 students from Hawaii, Porto Rico and the Philippine Islands, and 314 students from foreign countries.

NUMBERS OF STUDENTS BY CLASSES

In Table 3, on page 506, the students enrolled in each college are shown by classes. This permits one to see whether the attendance at each college is increasing or decreasing. The total attendance for the first year was 3,104 as compared with 4,283 last year and 4,107 in 1917. This reduction in the number of freshman students was largely due to the volunteering or drafting of premedical and freshman students during the war. The second year attendance was 3,587, as compared with 3,521 last year, and 3,117 in 1917. The third year attendance was 3,272, as compared with

TABLE 5—MEDICAL COLLEGE ATTENDANCE

Year	Non-sectarian	Homeopathic	Ecclectic	Physio-Med.	Non-descript	Total

1916.....	14,121	658	263	11,042
1917.....	12,925	580	250	13,754
1918.....	12,737	549	428	...	225	13,660
1919.....	12,259	397	86	...	410	13,052

2,893 last year, and 2,866 in 1917. The enrolment of the fourth and fifth (intern) years, combined this year, is 3,089, as compared with 2,933 last year, and 3,674 in 1917. The sophomore, junior and senior class enrolments, therefore, show increases, respectively, of 66, 379 and 741 over the enrolments in those classes last year. This indicates that the college enrolments have largely been readjusted under the higher entrance requirements and, had it not been for the war, the total enrolment in the medical schools would also have shown an increase.

EXISTING AND EXTINCT MEDICAL COLLEGES

Table 4, on pages 507 to 512, gives (a) the different names under which each existing college has been known, the years when the institution was so known, the years when it had (or did not have) graduates under that title and a reference to any previous or subsequent names under which it existed; (b) similar

licensing boards in their respective states, or in regard to which there is doubt as to whether any classes were ever held, have been omitted from the above list. Reference to such institutions can be obtained in the American Medical Directory.

NUMBER OF MEDICAL STUDENTS

The total number of medical students (Table 5) in the United States for the year ending June 30, 1919, excluding premedical, special and postgraduate students, was 13,052, a decrease of 578 below last year. It is noteworthy (Table 13, page 513) that in the high grade (Class A) medical colleges the percentage of all students has increased. Of the total number of students, 12,259 (93.9 per cent.) were in attendance at the nonsectarian (regular) colleges, 397 (3.0 per cent.) at the homeopathic, 86 (0.7 per cent.) at the eclectic, and 310 (2.4 per cent.) were enrolled in three nondescript colleges. These three colleges consist of two semi-osteopathic and one nominally

eclectic affair. Two of them are outlawed in their home state—Missouri—and one is in Massachusetts, which has a feeble medical practice law. None of them, therefore, is subject to rigid laws or regulations. One of them, the Kansas City College of Medicine and Surgery, exists only by the enjoyment of special privileges obtained through a sectarian licensing board in an adjoining state, the Eclectic Board of Arkansas!

* None of the graduates of nondescript colleges during the last two years was reported to have a collegiate degree.

NUMBER OF MEDICAL GRADUATES

The total number of graduates for the year ending June 30, 1919, was 2,656, a decrease of 14 below 1918. The number of graduates from the nonsectarian colleges was 2,423 or 31 less than last year. The number from the homeopathic colleges was 89 or 25 less than last year, and from the eclectic colleges there were 28 graduates, or 14 less than last year. The three nondescript colleges had 116 graduates.

GRADUATES HOLDING DEGREES IN ARTS

Of the 2,656 medical graduates, 1,180 (see Table 12) held also degrees in arts or science. This total includes those taking the combined courses in art- or

science and medicine. This year 44.4 per cent. of all graduates held collegiate degrees, as compared with 38.4 last year, 32.5 per cent. in 1917, and 26.9 per cent.

in 1916. This increase is what was expected under the general adoption by medical schools of the entrance requirement of two years of college work. In 1910 it is noteworthy that only 15.3 per cent. of the graduates show this evidence of higher preliminary qualifications. Of the 2,423 nonsectarian school graduates, 1,162, or 48.0 per cent., were reported to have bac-

* Information not furnished by six Class C colleges in 1918 and five in 1919.

calaureate degrees; of the homeopathic graduates 16, or 18.0 per cent. were so reported, and of the eclectic graduates this year 2, or 7.1 per cent. held such degrees. Of the 116 graduates of the nondescript colleges not one was reported as holding a bachelor's degree in arts or science. As will be noted by referring to Table 12, of the 1,180 graduates holding baccalaureate degrees, 175 the largest number—came as last

(Continued from page 503)

WOMEN IN MEDICINE

During the past year there were 686 women studying medicine, or 105 more than last year, and 76 more than in 1917. This increase is probably due to the war emergency and the resulting demand for physicians. The percentage of women to all medical students this year is 5.2, a larger percentage than that of any previous year. There were 107 women graduates this year, one more than last year, but 16 less than in 1917. Of all the women matriculants, 66 were in attendance at the one medical college for women, while 620 (90.1

H, Homeopathic; F, Eclectic; N, Nonscript.

per cent.) were matriculated in the fifty-nine coeducational colleges. From the one women's college there were 7 graduates, while 100 (93.4 per cent.) secured their degrees from coeducational colleges. This increase of women students in educational colleges is not surprising, since in recent years some of the largest and oldest medical schools, as Columbia, Tulane, the University of Pennsylvania, Harvard and Western Reserve University (and McGill University in Canada), have thrown open their doors to women.

NUMBER OF COLLEGES

Since June 30, 1918, five colleges (mentioned on page 514) were closed, leaving 85 still existing, of which 76 are nonsectarian (regular), 5 are homeopathic, 1 is eclectic and 3 are nondescript. Two of the nondescript colleges are not recognized by the licensing board of Missouri, the state in which they are located.

LENGTH OF TERMS

During the last nineteen years there has been a decided lengthening of college terms. This has reference to the weeks of actual work exclusive of holidays.

* Others only the first two years of the medical course.
 † Reported fraudulent or not in good standing in the state in which the college is located.

1. Sometimes referred to as the "Fairfield Medical School."
 2. From the 15th and 1878-80 this college bore the title: "Homeopathic College of Physicians and Surgeons."

3. Graduated its last class in 1914 when clinical teaching was abandoned.

4. Removed to Kansas City, Kansas, in 1907, changed its name in 1908 to the Western Eclectic College of Medicine and Surgery; returned to

Kansas City, Mo., in 1909 and resumed its former title. Was reported not recognized by the Missouri State Board of Health. Extinct 1918.

5. This school in 1895 was merged with the Central Medical College, St. Joseph, Missouri, taking the name of the Ensworth-Central Medical College. In 1905, however, this college resumed the name of the Ensworth Medical College. It became extinct in 1914.

6. This was the medical department of Fort Worth University 1894 to 1911; of the Texas Christian University 1911 to 1918.

7. This was the medical department of the Central University of Kentucky.

* Offered only the first two years of the medical course.

† Reported fraudulent or not in good standing in the state in which the college is located.

21. Was known as St. Louis College of Medical and Natural Sciences from 1855 to 1879; as Humboldt Institute from 1879 to 1896, and as Humboldt Medical College 1896 to 1899.

22. From 1841 to 1845 was known as the Medical Department of La Porte University.

23. In 1887 this college became the medical department of Drake University with the title the Iowa Medical College, Eclectic; also known as the Iowa Eclectic Medical College. Name changed to Drake University College of Medicine in 1903.

24. Kansas City College of Medicine and Surgery claims to be an eclectic medical college, but is reported not recognized as such by the National Eclectic Medical Association. It is an offshoot of the Eclectic Medical University, an institution which during its existence was rated in Class C by the Council on Medical Education. The new college has

refused instructions by the Council on Medical Education and is reported not recognized by the governing board of Missouri. Its home state and thirty-two other states.

25. This became the Medical Department of Washington College in 1902. 26. This was the medical department of Shaw University. The last class graduated in 1911 when it discontinued clinical teaching. It was closed in 1918.

27. This was the medical department of Collier University from 1911 to 1915 when the relationship was cancelled. It ended in 1918.

28. This was the medical department of Butler University from 1870-1882 and of the University of Indianapolis from 1882 to 1905.

29. Because the medical department of the University of Cincinnati, in 1890, retained its former name till 1909 when it merged with the Miami Medical College to form the Ohio Miami Medical College of the University of Cincinnati.

30. This institution and the Medical College of South Carolina were conducted as separate institutions from 1857 to 1858 when they were merged.

¹ Officers only the first two years of the medical course.

² Increased medical teaching in 1918 but retains a nominal existence and part in order to grant degrees to the three remaining classes which are completing their medical instruction elsewhere.

³ This was the medical department of Central Tennessee College which in 1906 became Walden University. The relationship was cancelled in 1910.

⁴ The Middlesex College of Medicine and Surgery is a nonsectarian institution which for several years has occupied the same building with the Massachusetts College of Osteopathy and, on inspection, the two would be considered as one institution. It has attained liberal advanced standing for courses taken in osteopathic institutions. It secured the old, abandoned charter of the Worcester Medical College of Boston otherwise it could hardly have obtained a charter under the State laws now in effect. The chartering of educational institutions in Massachusetts. Its profession was an eclectic, but no medical after education in 1918 which had a rather precarious existence. It underwent a reorganization in 1875, moved to Boston in 1877, returned to Worcester in 1878 and has since been a law medical school which has affiliated itself with schools of dentistry, pharmacy, chiropody, optometry, etc., under the high sounding title of the "University of Massachusetts." According to report, the latter has not secured authority from the State to grant degrees in arts or sciences and its name has not been found on the list of colleges or universities approved by any recognized standardizing agency. The medical school is rated in Class C by the Council on Medical Education and is reported as not recognized by the medical licensing boards of thirty-six states.

⁵ Degrees from 1881 to 1887 inclusive were granted by the University of Minnesota. It was the medical department of Hamline University from 1887 to 1911 to which the University of Minnesota transferred the three remaining classes completed their instruction in the University of Minnesota Medical School with which it was merged, but Hamline University granted the degrees.

⁶ Was an all-graduate body only until 1888 when it absorbed the consolidation of the Saint Paul Medical College and the Minneapolis Hospital College.

⁷ Officers only the first two years of the medical course. Taught clinical courses at Wakefield during the session of 1908-10 and in 1910 graduated its one class. Clinical teaching was then abandoned.

⁸ Sometimes known as the McDowell Medical College.

⁹ No classes were graduated in 1887, 1898, 1899 to 1893 inclusive, 1887 to 1889 inclusive from 1880 and 1881. From 1871 to 1875 was located in St. Louis. Reorganized at Columbia in 1875. Last class was graduated in 1909 when clinical teaching was discontinued.

¹⁰ The University of Nashville Medical Department and Vanderbilt University Medical Department merged in 1874. In 1908 and 1909 granting degrees was given to a portion of the class. Relationship dissolved in 1909.

¹¹ Similar union with the University of Tennessee Medical Department 1909 to 1911.

¹² Taught only the subjects of the first two years of the medical course until 1906 when the clinical department was established.

¹³ From 1901 to 1902 this was the medical department of Omaha University.

¹⁴ In the last few years of its existence this college is reported to have been fraudulent.

* Offers only the first two years of the medical course.

42. The charter of this institution passed into the hands of individuals who sold, or offered for sale its diplomas for a year or two after the college had ceased to exist. Most of such diplomas which were discovered were dated as of 1914.

43. Graduated one class of four students.

44. Known sometimes as "Pope's Medical College."

45. Was conducted as a preparatory school from 1871 to 1879.

46. Taught work of third and fourth years of the medical course supplementary to the two year course given by the Indiana University School of Medicine with which it was affiliated.

47. This school was organized as the College of Physicians and Surgeons but before a year had passed assumed the title, University College of Medicine.

(Continued from page 506)

Prior to 1904 the majority of colleges had sessions of twenty-eight weeks or less. For four years no colleges have had sessions shorter than twenty-nine weeks, and this year only one college reported a session as short as thirty weeks. Sessions of from thirty-three to thirty-six weeks were reported by 67, or 78.9 per cent., of all colleges.

TUITION AND OTHER FEES

Attention is called to Table 1, on pages 500-502, to the amount charged by the various medical colleges per annum for tuition, matriculation, laboratory and graduation fees for each student. In Table 11, the eighty-five colleges have been grouped according to the amount of fees charged and according to their classification by the Council on Medical Education in Classes A, B and C. Fourteen colleges charge fees of \$100 or less per year; thirty-six between \$100 and \$175, and thirty-five charge above \$175. Of the fourteen colleges charging \$100 or less, eleven (75 per cent.) are listed among Class A (acceptable) colleges² by the Council

48. Taught only the first two years of the medical course operating under the charter of the Chicago College of Medicine and Surgery.
* Offers only the first two years of the medical course.

on Medical Education; two are Class B colleges and one is rated in Class C. The eleven Class A colleges having these low fees are the schools of medicine of the state universities of Colorado, Iowa, Kansas, Michigan, Missouri, North Dakota, South Dakota, Texas, Utah, West Virginia and Wisconsin. On the other hand, five colleges listed by the Council in Class C charge fees of from \$100 to \$175 per year for each student, and one exacts fees of \$200. Diplomas from Class C colleges are reported as not recognized by thirty-three to thirty-nine state licensing boards.³ No intelligent student would knowingly spend his time and money in a low-grade college, the diplomas of which are not recognized by many states, when in the same time, and for even less money, he could attend one of the best-equipped colleges, the diplomas of which are recognized everywhere. Although forty-six colleges listed in Class A charge fees ranging from \$150 to \$275 per year for each student, the actual expense for teaching that student for the year in these colleges

³ See THE JOURNAL A. M. A., April 19, 1919, p. 1148, Table D, which shows to what state diplomas granted by various colleges are not recognized as an acceptable qualification for the license to practice.

amounts to three or several times the fee charged. In fact, accurate data secured from eighty-two medical colleges show that the average amount received each year from the individual student was \$150, while the average amount actually expended in the training of that student for a year was \$419. This larger expenditure is possible because the colleges receive either state aid or private endowment. This shows that no medical college can properly teach medicine on the income received from fees alone.

COLLEGES, STUDENTS AND GRADUATES BY STATES

Illinois formerly had the largest number of medical colleges (Table 12), but for the last three years the

first place has been held by New York, where there are still eight colleges. Illinois, Missouri and Pennsylvania have six colleges each; Massachusetts and Ohio have five each, and California and Tennessee have four each. Of Class C colleges, however, Missouri has three,

Massachusetts has two, and there is one each in Illinois and Tennessee. In Missouri the Class C colleges are not recognized by the local state licensing board and exist because that board does not have or does not exert the power to have their charters revoked.

For the last three years New York has had the largest number of students enrolled, this year having 2,272, followed by Illinois with 1,558 and Pennsylvania with 1,364. New York leads also in the number of graduates, having reported 450, followed by Pennsylvania with 358, Illinois with 247, Missouri with 229, and Massachusetts with 218.

QUALIFICATIONS OF STUDENTS AND GRADUATES

Table 13 shows the students and graduates of the last six years grouped according to the rank of the

colleges in the classification of the Council on Medical Education. Note that during the seven years the percentage of students enrolled in Class A colleges has increased from 65.4 to 87.9 and that for the last three years also the total numbers of students in attendance at these schools has increased from 11,317 to 11,466. Note, on the other hand, both the percentages and the totals of students enrolled in Class B and Class C colleges have been reduced. The percentage of students in Class B colleges has been reduced from 24.4 to 8.3 and in Class C colleges from 10.2 to 3.8. Of graduates, also, the percentage in Class A colleges shows an increase, while in Class B and Class C colleges there has been a decrease. The reduction in the total number of students and graduates, therefore, has been largely at the expense of the lower grade colleges, while the numbers of students and graduates in the higher grade colleges are actually increasing.

COLLEGE NOTES

Colleges Closed.—Five medical schools have been closed during the year. The College of Physicians and Surgeons, San Francisco, has discontinued the teaching of medicine but will retain a nominal existence for three years so as to grant degrees to the students of the three remaining classes who are completing their medical education in other schools. The College of Homeopathic Medicine of the State University of Iowa has been abolished by the Iowa legislature and in its stead an elective chair in homeopathic materia medica and therapeutics has been established in the State University of Iowa College of Medicine. Lincoln Medical College, Eclectic, Lincoln, Neb., has been reported closed. The Fordham University School of Medicine, New York City, was closed recently by the board of trustees of Fordham University on the plea that funds for the proper maintenance of the school were lacking. Leonard Medical School, the medical department of Shaw University, an institution for colored students located at Raleigh, N. C., has been closed.

Special Items Concerning Medical Education

Arkansas.—The University of Arkansas Medical Department, Little Rock, has discontinued the teaching of the clinical years and as a consequence the Council on Medical Education has rated the institution in Class A. The lower rating heretofore held by the school was due largely to the serious conditions in clinical teaching.

California.—The trustees of the University of Southern California have voted to set aside \$250,000 for the medical department to be used for new buildings and equipment.

Colorado.—The University of Colorado School of Medicine: The Phipps Loan Fund of \$5,000 was established in 1918 by Mr. L. C. Phipps and Mr. L. C. Phipps, Jr. Several loans are available from it each year for the benefit of promising students of the second, third or fourth years of the school of medicine who are in need of such assistance to enable them to continue their medical education.

Connecticut. Yale University School of Medicine has enlarged its medical library, providing more space for books and for the reading room. There are now 26,000 volumes in the library, including 14,000 bound volumes of medical journals and society transactions. There are over 250 medical periodicals, including both American and European journals. The library contains the "Index Medicus," the "Surgeon-General's Catalogue," and the "Quarterly Cumulative Index." A part of the library was donated to the medical school by the New Haven Medical Society.

—A special gift of \$50,000 was received from the family of the late Anthony N. Brady, for the equipment of the Brady Laboratory.

—A fund of \$80,000 to be known as the physiologic laboratory building fund, to be used ultimately for the construction of a physiologic laboratory and pending this the

income to be used for the benefit of the department of physiology, has been donated by Mr. and Mrs. Howard H. Spaulding, Jr., Chicago, who gave \$50,000; Mr. Benjamin H. Throop, who gave \$25,000, and Mr. J. Ogden Armour, Chicago, who donated \$5,000.

—In memory of Capt. Chauncey B. Keep, and to be used as an endowment for an infirmary for Yale University, a donation of \$54,000 in securities was made by Mr. and Mrs. Chauncey Keep and Mrs. Katherine Keep of Chicago.

Illinois.—Plans for the resumption of the preliminary work for the new medical college and hospital buildings for the University of Chicago have again been taken up. The new medical school will be constructed on the property owned by the university on the south side of the midway, and the first building to be erected will be a hospital and dispensary to cost \$1,000,000. The school for practitioners will be located near Rush Medical College, and the hospital will be known as the Albert Merritte Billings Hospital. The buildings planned will cost \$17,000,000.

Indiana.—The new medical school building of Indiana University at Indianapolis will, it is announced, be completed and ready for occupancy by the opening of the school year in September. The reports that the entire medical course will be taught at Indianapolis are denied and the premedical courses will be given in Bloomington as before.

Kentucky.—The Medical Department of the University of Louisville received from one of its faculty members a gift of \$5,000, payable \$500 annually. The first instalment will be expended in the equipment of a research laboratory in which diagnostic problems of medical and surgical cases will be worked out.

Massachusetts.—The Medical School of Harvard University received an anonymous donation of \$50,000 for the establishment of the James C. Melvin fund for tropical medicine, the income to be used for research in medicine. The medical school has also received the income on the residuary estate of Horace Fletcher, to be used to "foster knowledge of healthful nutrition." By the will of J. Ewing Mears \$100,000 was received for the study of methods to reform and cure criminals and mental defectives by surgery.

Michigan.—The legislature appropriated \$1,000,000 with which to start a new 800 bed hospital to be connected with the University of Michigan Medical School. It is expected that the building and equipment will cost between \$2,000,000 and \$3,000,000. It will be so constructed that building operations can be stopped at any story and the part that has already been completed can be used while the upper stories are being finished.

Missouri.—The Washington University School of Medicine, in addition to several smaller gifts for special investigations and similar purposes, has received a fund of \$300,000, one half from the general education board and one half from a friend of the university, for the endowment of the department of pharmacology. With this fund this department also will be established on the whole time university basis from the opening of the next session. Other departments of the school which have been placed on the university basis are medicine, surgery, pediatrics, pathology and bacteriology, physiology, biological chemistry and anatomy.

Nebraska.—A new laboratory building is being completed on the campus of the University of Nebraska College of Medicine. This building will house the departments of physiology, pharmacology and biochemistry. The general animal house for all three departments as well as for experimental surgery occupies a fifth floor, and includes a large operating room for animals. The cost is approximately \$150,000.

—Through the will of Clementine C. Conkling, property in the city of Omaha valued at \$25,000 has been bequeathed to the University of Nebraska College of Medicine. The income from this property will probably be devoted to the support of a research fellowship in surgery. The state appropriations for the medical college and hospital maintenance and equipment for the biennium ending April, 1921, totals \$389,000.

New York.—At the meeting of the trustees of Columbia University, Nov. 4, 1918, it was announced that the New York Polyclinic Hospital had offered to transfer its property to Columbia University, to be maintained and perpetuated for the public service and for advanced research in medicine and surgery. The trustees of Columbia University adopted resolutions, receiving the proposal and appointing a subcommittee to arrange the detailed terms and conditions of accepting the gift.

—Columbia University College of Physicians and Surgeons has received \$9,000 from the trustees of the East River Homes Foundation, to be applied toward work in tuberculosis; \$5,000 from an anonymous donor to be used in surgical research; \$1,000 each, to the funds to provide for the admission of women to the medical school, William H. Moore, Arthur Curtiss James, Elizabeth Waterbury, Forrest S. Bryden, J. M. Wallace, D. G. Reid, and F. L. Hines. A donation of \$1,000 was also received from Mrs. V. Everett Macy for additions to the medical school buildings.

—The Long Island College Hospital has been given a farm for keeping animals used in research, by an anonymous benefactor. Experimental work has already been begun on low influenza, diphtheria and chickenpox.

—The New York Post-Graduate Medical School and Hospital received \$25,000 by the will of Frederick Mead.

—The University of Buffalo has set aside \$100,000 and purchased property at a cost of \$17,500 with the intention of erecting new laboratories for the medical department. Construction will be begun at the earliest possible date. The new City Hospital on Grider Street is now available for teaching. Another unit is to be added to this hospital, which, when completed, will provide altogether about 1,200 beds.

—The New York Homeopathic Medical College and Flower Hospital received during the last year a gift of \$110,000 and also a new hospital building of 100 beds; value \$150,000. Furthermore, the alumni of the college have pledged to contribute \$30,000 yearly for the next five years for the maintenance of the college, in addition to the regular sums received from the students and from the trustees.

Ohio.—Two years ago a plot of land consisting of about 15 acres was purchased as a site for the new buildings of the School of Medicine of Western Reserve University; for a new Lakeside Hospital, and for a babies' and maternity hospital. It was planned to create a group of hospital and medical school buildings to make an ideal plant for the teaching of medicine. This tract is situated next to the literary departments of Western Reserve University and the Case School of Applied Science. Although the war has postponed the erection of these buildings, Lakeside Hospital lately received some contributions and bequests which will hasten the buildings. By the will of the late Col. Oliver Payne a gift of \$1,000,000 came to Lakeside to be used at the discretion of the trustees. By the will of the late Mr. W. S. Tyler, Cleveland, a trustee of Lakeside, a bequest of \$200,000 was provided for the erection and endowment of a maternity ward on the new site. Mr. Samuel Mather, president of Lakeside, opened the new building fund of the hospital by a gift of \$350,000. There is also a fund held by the trustees of Lakeside for the benefit of the children's and maternity wards amounting to over \$150,000.

—The faculty of the Western Reserve University School of Medicine voted to admit women at its session, beginning Oct. 2, 1919.

—The University of Cincinnati has established in its college of medicine a department in industrial medicine and public health. Under the plans submitted, \$100,000 is to be raised by the citizens' committee on finance, for the support of this department for five years. The training which will be received in this department will make the students competent social and medical engineers and will also enable them to educate the general public as to the value of good health. The course in the new department will be started in October and will be open to graduates in medicine. A portion of the instruction will be given at the college and part at various industrial establishments along the lines now practiced in the cooperative course.

Oklahoma.—The appropriation of a \$200,000 building for the hospital provided in 1917, for the University of Oklahoma School of Medicine, was supplemented by an appropriation in January, 1919, of \$56,929.87 which is to complete the building and provide furnishings. The hospital will be opened by the beginning of the next session in October.

Oregon.—The first unit of the University of Oregon Medical School, consisting of a reinforced concrete structure, 200 feet by 65 feet, has been completed and occupied. Ground has been deeded the county which will provide ample space to construct an affiliated hospital on the 20 acre campus. The construction of this hospital was begun in July.

Pennsylvania.—The Hahnemann Medical College of Philadelphia has received \$40,000 from Mr. Walter E. Hering to be known as "The Constantine Hering Fund"; the income of which is to be used for financially assisting deserving students to obtain their medical education. The college also

received from the same donor \$200,000 for research work in the fight against influenza.

—The Jefferson Medical College received \$5,000 for the endowment of a free scholarship, and \$10,000 by the will of Harriet Blanchard.

Tennessee.—The board of trustees of the University of Tennessee voted \$100,000 to the medical school to be used for a new laboratory building to be erected in the rear of the Memphis City Hospital. The new building will have laboratories for pathology, bacteriology, chemistry and physiology.

—The General Education Board and the Carnegie Foundation for the Advancement of Teaching have each given \$150,000 for the endowment of Meharry Medical College, Nashville, after the Methodist Episcopal Church had raised \$200,000, which makes a total of \$500,000.

Vermont.—The General Assembly of the State has provided fifty scholarships of \$100 each, available to regular resident students of the University of Vermont College of Medicine whose work is satisfactory and who are in need of financial assistance.

Virginia.—The University of Virginia Department of Medicine will be closely affiliated with the tuberculosis sanatorium established at Charlottesville by the State Board of Health. The fourth year students will take part of their clinical work at this sanatorium.

—The Memorial Hospital No. 2 for colored patients and the Dooley Hospital for contagious diseases, both owned and controlled by the Medical College of Virginia, will be opened early in the fall. The buildings cost respectively \$225,000 and \$65,000, and were built by subscriptions of the citizens of Richmond and by Major James H. Dooley.

Washington.—A plan to build a hospital on the campus of the University of Washington, Seattle, to cost a million dollars and which is to form the nucleus for a medical department of the university, was proposed and endorsed at the meeting of the Kings County Medical Society.

Wisconsin.—The Marquette University of Milwaukee has succeeded in raising its medical school endowment fund of \$1,000,000, one-third of which was donated by the Carnegie Foundation for the Advancement of Teaching. The income from this fund is to go for the salaries of teachers and maintenance and cannot be used for buildings, additional funds for which are now being sought.

General Items.—The General Education Board of the Rockefeller Foundation reports appropriations aggregating \$1,108,525 during 1918-19 to various educational institutions throughout the United States. Of this sum the largest amounts were given for medical education, \$400,000 being given to Johns Hopkins University Medical School for the endowment of a department of obstetrics, and \$150,000 to the Meharry Medical College at Nashville, Tenn.

Canada.—The University of Toronto has received a bequest of \$50,000 by the will of the late Dr. Julius Mickle, London, England, a former graduate of the university. This amount will be divided into two fellowships, one in honor of the donor's father and mother. The former will consist of the income from \$25,000, to be awarded to the person who, during the preceding ten years, has done most to promote the sound practice of medicine, and this will be open to all the world. The other fellowship will be awarded to the student of the University of Toronto who passes highest in his or her third and fourth years.—An unnamed donor has given the University of Toronto \$10,000 through Mrs. McCrae Kilgour, Brandon, Man., in memory of her brother, the late Col. John McCrae, who was an alumnus of the university. This will be used for two scholarships to be given in alternate years to students from Guelph Collegiate Institute; failing one, then from any other institute in Canada.—The residue of the estate of the late Dr. Richard A. Reeve, Toronto, goes to the University of Toronto, but the amount is not definitely known as yet.—The president of the University of Toronto has asked all members of the clinical medical department to place their resignations in the hands of the newly appointed professor of medicine, Dr. Duncan A. L. Graham, preparatory to reorganization of the faculty. Dr. Graham will strive to bring about the more intimate correlation of laboratory and clinical methods for diagnosis and treatment of disease.—The department of medicine of the University of Toronto is to be the recipient of a gift of \$25,000 a year for a period of twenty-five years from Sir John and Lady Eaton. This is to provide for a full-time clinician in the department of medicine and a half-time clinician in pediatrics.—A recent endowment to the University of Toronto provides a sum of

between \$500,000 and \$750,000 for the establishment of four special chairs to be held by full-time professors. These chairs are, respectively, pediatrics, gynecology, orthopedic surgery, and a fourth to be determined.

—The Faculty of Medicine of Western University, London, Ont., is planning the erection of a new medical college building at an estimated cost of \$100,000.

—Queen's University, Kingston, Ontario, reports that an additional endowment of \$1,000,000 has been received for the general purposes of the university. Of this sum, the Carnegie Foundation gave \$250,000 on condition that \$750,000 be obtained from other sources. The medical faculty will benefit from this fund in proportion to its requirements, and it is proposed that several more full-time professors will be secured, and the departments of physiology, bacteriology and public health will be developed. A fund of \$200,000 is also available to be expended in the reconstruction of the hospital.

—A tablet was recently unveiled in the New Medical Building, McGill University, to the memory of nine medical students who lost their lives in France. Dr. George E. Armstrong, acting dean of the medical faculty, delivered an address as the tablet was unveiled.—Prof. J. George Adams, McGill University, is to leave that institution to accept the vice chancellorship of Manchester University, England.

Scotland.—The University of Glasgow has received from Mr. William Guthrie Gardiner and Mr. F. C. Gardiner an endowment for three chairs in the university, these being the chairs of bacteriology, organic chemistry and physiologic chemistry. The endowment amounts to £20,000, or \$100,000, for each chair, making a total of £60,000, or \$300,000.

South America.—New pavilions for the study of anatomy, histology and pathologic anatomy have been erected for the school of medicine in the University of Bogota, Colombia.

Egypt.—The Gordon Memorial College, now in its seventeenth year at Khartoum, Egypt, is proposing to found a medical school as a memorial to Lord Kitchener. About \$45,000 has already been collected for the purpose, mainly by subscriptions from natives in the Sudan.

GRADUATE COURSES IN PUBLIC HEALTH

Graduate courses in public health have been established in connection with eleven medical schools, the first of which was at the University of Pennsylvania in 1909, the latest that in connection with the medical department of the Johns Hopkins University which began its course in 1918. Two institutions, the University of Colorado and Tulane University, have suspended their courses, at least for the present. Three others report no students during the past year, giving the war as a reason. Five of the schools have courses leading to the degree of Doctor of Public Health (Dr. P. H.); three after a two-year course and two after a one-year course. The University of California offers the degree of Graduate in Public Health (Gr. P. H.) after a two-year course instead of the degree of Dr. P. H. The degree of Certified Sanitarian (C. S.) after a one-year course is offered by the University of Pennsylvania to graduates of colleges of arts and sciences. The degree of Master of Public Health (M. P. H.) is offered after a one-year course by the Detroit College of Medicine and Surgery and the University of Wisconsin Medical School. The Master in Arts in Public Health [M. A. (P. H.)] is offered by the University of California Medical School, and the Master in Science in Public Health [M. S. (P. H.)] by the University of Michigan. The courses offered by the eleven medical schools are as follows:

THE UNIVERSITY OF CALIFORNIA: Courses began in 1915; number of instructors, 23; three courses leading to degree of Gr. P. H.: (a) a four year course covering three years in the college of letters and science and one year in the medical school; (b) a two year course covering one year in the college of letters and science and one year in the medical school for graduates of the college of civil engineering who have completed the work in sanitary engineering, and (c) a course of one and a half years, including one year in the college of letters and science, and a half year in the medical school for students who have completed three and a half years of the medical course. Completion of this third course gives the degrees of M.D. and Gr. P. H. The University of California also offers a one year course to graduates in art or sciences for the degree of Master in Arts in Public Health [M.A. (P.H.)]. Fees are \$150 each year. A thesis is required for the degree; students enrolled 1918-19, 15; no graduates. The course extends from August to May.

JOHNS HOPKINS MEDICAL SCHOOL: The School of Hygiene and Public Health was opened in October, 1918. There are 34 instructors. Four courses are offered: (A) A two year course leading to the degree of Dr. P. H., requiring for admission a bachelor's degree and a degree in medicine. The degree of M.D. and the degree of Dr. P. H. may be obtained in a combined course of five years. A thesis is required for graduation.

(B) A three year course leading to the degree of Doctor of Science in Hygiene requiring for admission a bachelor's degree and adequate

training in physics, chemistry, biology and the medical sciences, anatomy, physiology and pathology. A written and oral examination and a dissertation on the results of an independent investigation are required for graduation.

(C) A two year course leading to the degree of Bachelor of Science in Hygiene, the course consisting of combined work in the medical school and the School of Hygiene and Public Health. For admission the applicant must have completed at least two years of work in an approved college and have studied courses in physics, biology, inorganic and organic chemistry.

(D) A one year course leading to a certificate in public health is also offered to graduates of approved medical schools or graduates in arts or sciences who present evidence of satisfactory training in the physical and medical sciences.

The fees charged are \$250 per year. Altogether 16 students were enrolled during 1918-1919; no graduates. The course extends from September 30 to June 15.

MEDICAL SCHOOL OF HARVARD UNIVERSITY: The School of Public Health was opened in 1905; there are 40 instructors. The one year course is offered leading to a certificate in public health. For admission the applicant must have completed two years of work in a recognized medical school, or have received a bachelor's degree from an approved college or technical school, or have had special experience in public health work. In any instance he must show evidence of having completed satisfactory courses in physics, chemistry and biology and modern languages and the fundamental medical sciences. Although not a prerequisite, all candidates are advised to obtain a medical degree before specializing in public health work. Fees are \$250 per year; 70 students were enrolled during 1918-19; one graduate. Course runs from October to June.

DETROIT COLLEGE OF MEDICINE AND SURGERY: The course began in 1913 with ten instructors. A one year course leading to the degree of Master of Public Health (M.P.H.) is offered to graduates of approved medical schools. Fees are \$130 per year. No thesis required. No students enrolled during the past session. The course runs from September to June.

THE UNIVERSITY OF MICHIGAN MEDICAL SCHOOL: The graduate courses in public health were established in the University of Michigan in 1913. The number of instructors is approximately 10. Two courses are offered,—one to graduates in arts and sciences or medicine extending from one to two years, leading to the degree of Master in Science and Public Health; the other a course of from two to three years in length for graduates in arts or sciences and medicine, leading to the degree of Doctor of Public Health. For residents of Michigan the fees consist of \$10 matriculation and \$49 for men students and \$45 for women; for non-residents of Michigan, matriculation \$25 and an annual fee of \$49 for men and \$65 for women. A thesis is required for the degree of Dr. P. H. There is a summer session but the regular session extends from October 1 to July 1. No students were enrolled during the last session owing to war conditions.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE: The graduate course in public health began in 1916 with approximately 30 teachers. Two courses are offered,—a one year course leading to the degree of Doctor of Public Health for graduates of approved medical schools, and a correspondence course of indefinite length, especially adapted for physicians who are health officers, leading to a certificate in public health. The tuition for the Dr. P. H. course is \$200 per year and for the certificate course, \$50. For the certificate course the last week must be spent in residence. There were 74 health officers reported as taking the correspondence course during the year. Four degrees of Dr. P. H. were granted during the year and 25 candidates completed the correspondence course. The course runs from October to June.

THE UNIVERSITY OF PENNSYLVANIA: The graduate courses in public health began in 1906; there are 13 instructors; two courses are offered,—a one year course for graduates in medicine, leading to the degree of Dr. P. H. and a one year course for graduates of arts or science leading to the degree of Certified Sanitarian. A thesis is required for graduation. The fees are \$150 per year. There were two students during 1918; one graduate. The course extends from October to June.

THE UNIVERSITY OF WISCONSIN: Graduate courses in public health began in 1910. There are eight teachers. Two courses are offered,—a one year course for graduates in medicine, leading to the degree of Master of Public Health (M. P. H.); the other a two year course for physicians, leading to the degree of Doctor of Public Health. Fees are \$50 per year for residents of Wisconsin and \$170 for non-residents. A thesis is required for graduation. There were no students and no graduates during the last year owing to war conditions.

Uniform Requirements in 1920-21

On February 28, 1919, a conference of representatives from a number of universities in the country was held at New Haven, Conn. The object of the conference was to reach an agreement on the matters of curriculum, degrees and certificates in connection with teaching and awards in Public Hygiene. As a result of certain recommendations at this conference the following changes will probably be made to take effect with the Session 1920-21:

1. That the degree of Doctor of Public Hygiene (for which the abbreviation shall be Dr. P. H.) for graduates in medicine shall be awarded after two years of work done under academic direction, of which one year at least shall be in residence, and that the requirements for the degree shall include class work, practical field work, and an essay based on individual study of a particular problem.

2. That the degree Doctor of Philosophy or Doctor of Science in Public Hygiene shall be conferred on students who hold the bachelor's degree from a college or technical school of recognized standing, and have satisfactorily completed not less than three years of graduate study. It is understood that this degree is based on a knowledge of physics, chemistry, biology, anatomy, physiology, physiologic chemistry, pathology and bacteriology.

3. That the Certificate in Public Hygiene shall be granted for not less than one academic year of work to those who have satisfactorily completed two years of work in a recognized medical school or who have received a bachelor's degree from a recognized college or technical school, provided they have pursued satisfactory courses in physics, chemistry, biology and general bacteriology.

4. That the degree of Bachelor of Science in Public Hygiene shall be given for the completion of a four years' course, the last two years of which shall be devoted to the fundamental sciences associated with hygiene.

5. That the fee for the course shall be advanced to \$250 for the course leading to a degree or certificate and to \$35 for instruction in any single branch of the course.

GRADUATE MEDICAL SCHOOLS

There are now eighteen graduate medical schools in the United States. These are commonly referred to as post-graduate medical schools. Of these institutions, seven are connected with universities in which the graduate teaching is, or will be, as thoroughly and scientifically given as are the courses of the undergraduate medical school. The universities having graduate schools are the Universities of Alabama, California, Tulane, Harvard, Minnesota, Columbia and Pennsylvania.

The University of Chicago has received a generous endowment preparatory to the establishing of a large graduate school. Active steps toward this end have been delayed by the war.

Several of the undergraduate medical schools give graduate courses to a greater or less extent. Following is the complete list of the graduate medical schools:

ALABAMA

GRADUATE SCHOOL OF MEDICINE OF THE UNIVERSITY OF ALABAMA, Ave. F and 20th St., Birmingham. Organized 1915. Formerly the Birmingham Medical College. The dean is Dr. Lewis C. Morris, Empire Bldg.

CALIFORNIA

SAN FRANCISCO POLYCLINIC AND POST-GRADUATE SCHOOL, 1535 Jackson St., San Francisco. The dean is Dr. H. D'Arcy Power.

GRADUATE SCHOOL OF MEDICINE OF THE UNIVERSITY OF CALIFORNIA, Buena Vista and Alpine Sts., Los Angeles. Organized 1914. Formerly the University of Southern California College of Medicine. The dean is Dr. George H. Kress.

ILLINOIS

CHICAGO POLYCLINIC, 219-221 W. Chicago Ave., Chicago. The secretary is Dr. Malcolm L. Harris, 32 N. State St.

ILLINOIS POST-GRADUATE MEDICAL SCHOOL, 1844 W. Harrison St., Chicago. The secretary is Dr. James A. Clark.

POST-GRADUATE MEDICAL SCHOOL, 2400 Dearborn St., Chicago. The secretary is Dr. Emil Ries, 77 E. Washington St.

CHICAGO EYE, EAR, NOSE AND THROAT COLLEGE, 235 W. Washington St., Chicago. The secretary is Dr. John R. Hoffman, 31 N. State St.

PROVIDENT HOSPITAL POST-GRADUATE SCHOOL, 16 West 36th St., Chicago. For colored physicians. The dean is Dr. George C. Hall.

LOUISIANA

NEW ORLEANS POLYCLINIC, Post-Graduate School of Medicine of the Tulane University of Louisiana, Tulane Ave. and Liberty St., New Orleans. The dean is Dr. Chas. L. Chassagnac.

NEW ORLEANS POST-GRADUATE SCHOOL OF MEDICINE, 135 South Rampart St., New Orleans. The secretary is Dr. Joseph A. Danna.

MASSACHUSETTS

HARVARD GRADUATE SCHOOL OF MEDICINE, 240 Longwood Ave., Boston. Organized 1912. Instructors in charge of the various departments of the medical school. Teaching as thorough and scientific as in the undergraduate school. Instruction throughout the year. The dean is Dr. Alexander S. Begg.

MINNESOTA

UNIVERSITY OF MINNESOTA GRADUATE SCHOOL OF MEDICINE, Minneapolis. Organized 1914. In 1915, the resources and facilities of the Mayo Foundation were added, with the staff, clinics, laboratories, library and records at Rochester, Minn. Instruction throughout the year. The dean is Guy Stanton Ford, Ph.D., Minneapolis.

NEW YORK

NEW YORK POST-GRADUATE MEDICAL SCHOOL, 24 Ave. and 20th St., New York City. The secretary is Dr. J. Bentley Squier.

NEW YORK POLYCLINIC MEDICAL SCHOOL, 341-51 W. 50th St., New York City. Is to be taken over and the work developed by Columbia University. The president is Dr. John A. Wyeth, 241 W. 50th St.

MANHATTAN EYE, EAR AND THROAT HOSPITAL AND MEDICAL SCHOOL, 210 E. 64th St., New York City. The secretary is Dr. Samuel J. Kopetzky.

SCHOOL OF OPHTHALMOLOGY AND OTOTOLOGY, 13th St. and 2d Ave., New York City. The secretary is Dr. George S. Rixson, 40 E. 41st St.

COLLEGE OF THE NEW YORK OPHTHALMIC HOSPITAL, 23d St. and Third Ave., New York City. The secretary is Dr. W. C. McKnight, 13 Central Park West.

PENNSYLVANIA

GRADUATE SCHOOL OF MEDICINE OF THE UNIVERSITY OF PENNSYLVANIA, Philadelphia. Organized 1916 by taking over the Medico-Chirurgical College of Philadelphia. The Philadelphia Polyclinic was merged in 1918. The dean is Dr. George H. Meeker.

STANDARDS OF THE COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION

SCHEDULE FOR THE GRADING OF MEDICAL SCHOOLS

Schools are rated on a civil service basis on a scale of 1,000 points. The data relating to each school are grouped under ten general heads in such a manner that the groups have as nearly equal weight as possible, each group allowing a possible 100 points (10 per cent.) out of a possible 1,000 points (100 per cent.). The revised schedule showing the general heads under which the data are arranged is as follows:

1. Character of curriculum, grading of course, sequence of subjects, supervision, administration, etc.
2. Medical school buildings; adaptability, light, heat, ventilation, cleanliness, etc.
3. Laboratory facilities and instruction.
4. Dispensary facilities and instruction.
5. Hospital facilities and instruction in medicine, surgery, obstetrics, and gynecology.
6. Hospital facilities for instruction in medical specialties and provision for clinical clerkships, necropsies, etc.
7. Full-time instructors and assistants with special reference to their special qualifications and evidences of their work, including research.
8. Faculty, number, qualifications and organization of, including the staff of teaching hospitals.
9. Library, museum, charts and special apparatus and evidences of the use made of them.
10. Showing of graduates at state board and other examinations and other evidences by which the training received is indicated.

It will be noted that financial income is not referred to in the ten heads outlined. It is quite evident, however, that no college can secure an adequate number of expert full-time teachers, provide well equipped laboratories, library and museum, and be conducted in accordance with present-day medical knowledge without a liberal income in addition to students' fees.

MEANING OF CLASSES A, B, AND C

Class A Colleges will, as heretofore, be those which are acceptable; Class B, those which, under their present organization, give promise of being made acceptable by general improvements, and Class C those

(a) Which require a complete reorganization to make them acceptable.

(b) Which do not keep satisfactory records of their students in regard to entrance requirements, attendance, grades in courses, division into classes and reasons for promotion.

(c) Which do not enforce their requirements in regard to admission (including those admitted to advanced standing), promotion and graduation.

(d) Which give the major portion of their instruction after 4 o'clock in the afternoon.

(e) Which are privately owned and conducted for profit.

(f) Which for other specific reasons are not eligible for inclusion in Class B.

ESSENTIALS OF AN ACCEPTABLE MEDICAL COLLEGE

(Revised to June 15, 1919)

The following outline of the essentials of an acceptable medical college was issued by the Council on Medical Education of the American Medical Association for its suggestive value in the rapid development in progress in the medical colleges of the United States. It also represents the standard by which medical colleges are measured in the Council's classifications.

REQUIREMENTS FOR ADMISSION

1. The minimum requirement for admission to an acceptable medical college is a four-year high school education or its full equivalent and two years of work in a college of arts and sciences approved by the Council, as follows:

I. High School Requirements

(a) For admission to the two-year premedical college course, students shall have completed a four-year course of at least fourteen units (fifteen after Jan. 1, 1920) in a standard accredited high school or other institution of standard sec-

ordinary school grade, or have the equivalent as demonstrated by examinations conducted by the College Entrance Examination Board, or by the authorized examiner of a standard college or university which has been approved by the Council on Medical Education. Unless all the entrance units are obtained by examination, a detailed statement of attendance at the secondary school, and a transcript of the student's work, should be kept on file by the college authorities. This evidence of actual attendance at the secondary schools should be obtained, no matter whether the student is admitted to the freshman or to higher classes.

(b) Credits for admission to the premedical college course may be granted for the subjects shown in the following list and for any other subject counted by a standard accredited high school as a part of the requirements for its diploma, provided that at least eleven units must be offered in Groups I-V:

SCHEDULE OF SUBJECTS REQUIRED OR ACCEPTED FOR ENTRANCE TO THE PREMEDICAL COLLEGE

Subjects	COURSE	Units*	Required
GROUP I, ENGLISH—			
Literature and composition.....		3-4	3
GROUP II, FOREIGN LANGUAGES—			
Latin.....		1-4	
Greek.....		1-3	
French or German.....		1-4	2†
Other foreign languages.....		1-4	
GROUP III, MATHEMATICS—			
Elementary algebra.....		1	1
Advanced algebra.....		1½	1
Plane geometry.....		1	1
Solid geometry.....		½	1
Trigonometry.....		½	1
GROUP IV, HISTORY—			
Ancient history.....		1½-1	
Medieval and modern history.....		1½-1	
English history.....		1½-1	1
American history.....		1½-1	
Civil government.....		1½-1	
GROUP V, SCIENCE—			
Biology.....		1½-1	1
Zoology.....		1½-1	1
Chemistry.....		1½-1	1
Physics.....		1	1
Physiography.....		1½-1	1
Physiology.....		1½-1	1
Astronomy.....		1½-1	1
Geology.....		1½-1	1
GROUP VI, MISCELLANEOUS—			
Agriculture.....		1-2	1
Bookkeeping.....		1½-1	1
Business law.....		1½-1	1
Commercial geography.....		1½-1	1
Domestic science.....		1-2	1
Drawing, freehand and mechanical.....		1½-2	1
Economics and economic history.....		1½-1	1
Manual training.....		1-2	1
Musical Appreciation or harmony.....		1-2	1

* A unit is the credit value of at least thirty-six weeks' work of four or five recitation periods per week, each recitation period to be not less than forty minutes. In other words, a unit represents a year's study in any subject in a secondary school, constituting approximately a quarter of a full year's work. A satisfactory year's work in any subject cannot be accomplished under ordinary circumstances in less than 120 sixty-minute hours, or their equivalent.

† Both of the required units of foreign language must be of the same language, but the two units may be presented in any one of the languages specified.

On the fourteen units of high school work (fifteen after Jan. 1, 1920), eight units are required, as indicated in the foregoing schedule; the balance may be made up from any of the other subjects in the schedule.

II. Premedical College Course

(c) Beginning Jan. 1, 1918, the minimum requirement for admission to acceptable medical schools, in addition to the high school work specified above, will be sixty semester hours of collegiate work in a college approved by the Council on Medical Education. The subjects included in the two years of college work should be in accordance with the following schedule:

SCHEDULE OF SUBJECTS OF THE TWO-YEAR PREMEDICAL COLLEGE COURSE		
Required Subjects:	Sixty Semester Hours* Required	Semester Hours
Chemistry (a).....		12
Physics (b).....		8
Biology (c).....		8
English composition and literature (d).....		6
Other nonscience subjects (e).....		12

1. A tentative list of approved colleges may be received on application.

Subjects Strongly Urged:

A modern foreign language (f).....	6-12
Advanced botany or advanced zoology.....	3-6
Psychology.....	3-6
Advanced mathematics, including algebra and trigonometry.....	3-6
Additional courses in chemistry.....	3-6

Other suggested Electives:

English (additional), economics, history, sociology, political science, logic, mathematics, Latin, Greek, drawing.

* A semester hour is the credit value of sixteen weeks' work consisting of one lecture or recitation period per week, each period to be not less than fifty minutes net, at least two hours of laboratory work to be considered as the equivalent of one lecture or recitation period.

SUGGESTIONS REGARDING INDIVIDUAL SUBJECTS

(a) *Chemistry*.—Twelve semester hours required (eight until Jan. 1, 1920), of which at least eight semester hours must be in general inorganic chemistry, including four semester hours of laboratory work. In the interpretation of this rule work in qualitative analysis may be counted as general inorganic chemistry. The remaining four semester hours (required after Jan. 1, 1920) may consist of additional work in general chemistry or of work in analytic or organic chemistry. After Jan. 1, 1922, organic chemistry will be required.

(b) *Physics*.—Eight semester hours required, of which at least two must be laboratory work. It is urged that this course be preceded by a course in trigonometry. This requirement may be satisfied by six semester hours of college physics, of which two must be laboratory work, if preceded by a year (one unit) of high school physics with laboratory work.

(c) *Biology*.—Eight semester hours required, of which four must consist of laboratory work. The requirement may be satisfied by a course of eight semester hours in either general biology or zoology, or by courses of four semester hours each in zoology and botany, but not by botany alone. This requirement may also be satisfied by six semester hours of college biology, including three semester hours of laboratory work, if preceded by a year (one unit) of high school biology or zoology with laboratory work.

(d) *English Composition and Literature*.—The usual introductory college course of six semester hours, or its equivalent, is required.

(e) *Nonscience Subjects*.—Of the sixty semester hours required as the measurement of two years of college work, at least eighteen, including the six semester hours of English, should be in subjects other than the physical, chemical or biologic sciences.

(f) *Foreign Language*.—A reading knowledge of a modern foreign language is strongly urged. French and German have the closest bearing on modern medical literature. If the reading knowledge in one of these languages is obtained on the basis of high school work, the student is urged to take the other language in his college course. It is not considered advisable, however, to spend more than twelve of the required sixty semester hours on foreign languages.

III. Approved Colleges of Arts and Sciences

A tentative list of colleges of arts and sciences approved by the Council on Medical Education has been prepared, and revisions of this list will be published from time to time. By an approved college (of arts and sciences) is meant one whose standing has been vouched for by some standardizing agency in whose methods the Council has confidence. To be recognized a college must have sufficient scientific equipment and maintain laboratories in the premedical sciences. It must have ample endowment to maintain a sufficient corps of teachers. Membership in some national organization or association of colleges will be favorably regarded by the Council and, in the absence of such membership, careful investigation will be made of the causes of exclusion. It must also maintain national standards for admission to its freshman class. Students must be required to complete a four-year high school course, and the requirements for admission to the premedical course must be no less than the requirements for admission to the regular B. S. course of the college.

Particular attention will be given to the character of high schools from which certificates are received. Colleges should recognize only certificates from high schools approved by commissions or boards of associations of colleges and secondary schools or other agencies approved by the Council. When such endorsement is lacking the college should be slow in accepting certificates without the support of entrance

examinations. Undue liberality in the acceptance of certificates from secondary schools unendorsed by approved standardizing agencies will be registered by the Council as a failure to comply with its requirements and the college will be dropped from the approved list.

PREMEDICAL COURSES IN MEDICAL COLLEGES— JUNIOR COLLEGES

1. Premedical college courses given in or by medical schools, or advance years taken in high schools, will not be considered as acceptable unless they have been investigated and approved by some association of colleges and secondary schools or other approved agency having to do with the standardizing of liberal arts colleges.

ADMINISTRATION OF ENTRANCE REQUIREMENTS

2. The admission of students to the medical school must be in the hands of a responsible committee or examiner whose records shall always be open for inspection.² Documentary evidence of the students' preliminary education should be obtained and kept on file. When the medical school is an integral part of a university, this work usually devolves on the university examiner. Unless the university examiner and his records are closely accessible, however, some officer at the medical school should obtain and keep on file the documentary evidence of each student's preliminary education, including both high school and collegiate work. It is particularly important that the records show that the required amount of work in the premedical sciences, including laboratory exercises, has been completed.

OTHER MEDICAL SCHOOL REQUIREMENTS

3. The college should require that students be in actual attendance in the college *within the first week* of each annual session and thereafter.

4. Actual attendance at classes should be insisted on except for good cause, such as for sickness, and no credit should be given for any course where the attendance has been less than 80 per cent. of the full time.

5. (a) Full advanced standing may be granted to students only for work done in other acceptable medical schools and in granting advanced standing there should be no discrimination against the college's full-course students. Official verification of the student's previous medical work should be obtained by direct correspondence with the college previously attended, and his preliminary qualifications should also be verified and recorded the same as for freshman students. (b) In *exceptional cases* students from Class B medical schools may be given advanced standing but not higher than *entrance* to the third year (junior) class, and no credit should be given in any subject except on recommendation of the head of the department teaching that subject. (c) In *exceptional cases* students from Class C colleges may be given advanced standing but not higher than *entrance* to the second year (sophomore) class, and then only after thorough examinations in all first year subjects have been passed.

SUPERVISION, EQUIPMENT, TEACHERS

6. There should be careful and intelligent supervision of the entire school by the dean or other executive officer who holds, and has sufficient authority to carry out, fair ideals of medical education as determined by the present day knowledge of medicine.

7. There should be a good system of records³ showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Records should also be kept showing readily the attendance of patients at the teaching hospitals and dispensaries; the maternity cases attended by students, and the postmortem cases used in teaching.

8. The college curriculum should be fully graded and should cover four sessions of at least thirty-two weeks each, exclusive of time required for matriculation and holidays, and at least thirty hours per week of actual work. The courses offered in the various subjects should be set forth by departments (anatomy, physiology, etc.) in the annual announcement, showing for each course its number, subject content, character (lecture, recitation, laboratory or clinic), length of time, when, where, and by whom given, and the amount of credit allowed. The courses for each class should also be clearly set forth in a printed class schedule, for the guidance of the students.

(a) The college should give two years of work consisting largely of laboratory work in well equipped laboratories of

anatomy, histology, embryology, physiology, chemistry (inorganic, organic and physiologic), bacteriology, pathology, pharmacology, therapeutics and clinical diagnosis. Present-day medical knowledge makes it essential that these subjects be in charge of full-time, well-trained teachers.

(b) Two years of clinical work, largely in hospitals and dispensaries, with courses in medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence. With the higher entrance requirements time is now available in the latter part of the second year for beginning courses in physical diagnosis and the principles of surgery.

(c) As soon as conditions warrant, relations should be established with a number of approved hospitals so that a fifth undergraduate year may be required to be spent by the student as an intern under the continued supervision of the medical school.

FACULTY

9. (a) The college should provide at least *eight expert thoroughly trained professors in the laboratory branches*, salaried so that they may devote their entire time to instruction and to that research without which they cannot well keep up with the rapid progress being made in their subjects.⁴ There should also be a sufficient number of assistants in each department to look after the less important details. For colleges having *sixty students or less* in each class, there should be at least *one full-time salaried assistant each in the departments of* (1) anatomy, (2) physiology, (3) pathology and bacteriology, and (4) physiologic chemistry and pharmacology, and *one additional assistant in each of these departments should be provided for each additional thirty students enrolled*. This represents a low average of the full-time assistants already employed by the acceptable medical colleges.

(b) The faculty should be made up of graduates of institutions recognized as medical colleges and who have had a training in all departments of medicine. Nonmedical men should be selected as teachers in medical schools only under exceptional circumstances and only when medical men of equal special capacity are not available. The faculty should be organized, each department having its head professor, its associate professor, assistant professor, instructor, etc., each having his particular subjects for the teaching of which he is responsible to the head of the department.

CLINICAL FACILITIES

10. (a) The college should own or entirely control a hospital, in order that students may come into close and extended contact with patients under the supervision of the attending staff. This hospital should be in close proximity to the college and have a daily average (for senior classes of 100 students or less) of not less than 200 patients who can be utilized for clinical teaching, these patients to be of such character as to permit the students to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties. In the use of this material *bedside and ward clinics* should be developed for sections of from five to ten students, and for the seniors, a certain number of patients in medicine, surgery and the specialties should be assigned to each student. A well supervised clinical clerk system should also be installed. The treatment and care of these patients should be particularly observed and recorded by the student under the strict supervision of the intern, or the attending staff of the hospital.

(b) The college should also have ample hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

(c) The college should own or control a dispensary, or outpatient department, the attendance to be a daily average of 100 patients (visits) (for senior classes of 100 students or less), the patients to be carefully classified, good histories and records of the patients to be kept and the material to

2. See "Meaning of Classes A, B and C," paragraph (c), on page 517.

3. These professors should have a definite responsibility in the conduct of the college, and their first and chief interest should be the training of medical students. It is suggested that four of these professors be placed at the head of the departments of (a) anatomy, (b) physiology and physiologic chemistry, (c) pathology and bacteriology, and (d) pharmacology and therapeutics. The other four may be assigned, one each, to (e) histology and embryology, under the department of anatomy, and to the departments of pathology and bacteriology, physiology and pharmacology, and to the departments of internal medicine and surgery.

4. Suggestions more in detail may be found in the "Report of the Committee on the Reorganization of Clinical Teaching," THE JOURNAL A. M. A., March 6, 1915. Reprint sent on application.

be well used. The attending staff should be made up of good teachers, should be well organized and be regular in attendance.

(d) At least six maternity cases should be provided for each senior student, who should have actual charge of these cases under the supervision of the attending physician. Careful records of each case should be handed in by the student.

(e) Facilities should be provided for at least thirty necropsies (for senior classes of 100 students or less) during each college session which are attended and participated in by senior students.

OTHER TEACHING FACILITIES AND FINANCES

11. The college should have a working medical library, to include the more modern text and reference books with the *Index Medicus* and thirty or more leading medical periodicals, the current numbers of which should be in racks or on tables easily accessible to the students; the library room should be properly lighted and heated, and open during all or the greater part of the day; it should be equipped with suitable indexes as well as with tables and chairs, and have a competent librarian in charge.

12. There should be a working medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed so that any specimen may be easily found and employed for teaching purposes. It is suggested that so far as possible with each pathologic specimen coming from postmortems there also be kept the record of the postmortem, the clinical history of the patient on whom the necropsy was held and microscopic slides showing the minute structures of the disease shown in the gross specimen. The museum furnishes an excellent means of correlating the work of the department of pathology with that of the clinical departments.

13. There should be sufficient dissecting material to enable each student individually to dissect at least the lateral half of the human cadaver, to provide cross-sections and other demonstration material and to allow of a thorough course for each senior in operative surgery on the cadaver.

14. For modern experimental laboratory work in physiology, pharmacology and bacteriology as well as for medical research, a supply of animals—frogs, turtles, rabbits and guinea-pigs, if not also cats and dogs—is essential. Proper provision, also, is necessary for the housing and care of such animals. In any use made of animals every precaution should be taken to prevent needless suffering, and work by students should be carefully supervised.

15. Each college should have a supply of such useful auxiliary apparatus as a stereopticon, a reflectoscope, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, a roentgen-ray and other apparatus now so generally used in medical teaching.

16. The college should show evidences of thorough organization and of reasonably modern methods in all departments, and evidences that the equipment and facilities are being intelligently used in the training of medical students.

17. A clear statement of the college's requirements for admission, tuition, time of attendance on the classes, sessions, courses offered and graduation should be clearly set forth, together with complete classified lists of its matriculants and latest graduating class in regular annual catalogues or announcements.

18. Statistics show that modern medicine cannot be acceptably taught by a medical school depending solely on the income from students' fees. No medical school should expect to secure admission to, or be retained in Class A, therefore, which does not have an annual income of at least \$25,000 in addition to the amount obtained from students' fees.

NOTE.—Correspondence from medical colleges regarding the above requirements is invited, and further suggestions or information available will be gladly furnished.

ENTRANCE REQUIREMENTS OF MEDICAL COLLEGES

Seventy-eight medical schools are now requiring, as a minimum for entrance, two years or more of work in a college of liberal arts in addition to a four-year high-school education. The years, respectively, when for each college the one-year and the two-year requirements became effective, and the rating of each college, are as follows:

College	ALABAMA	One Year	Two College
University of Alabama School of Medicine.....	1914	1915	A

Scholarships in Medical Schools

As evidence that provision is being made for worthy students, regardless of their financial status, 334 scholarships are reported this year in the following thirty-eight medical schools:

University of Alabama School of Medicine, Mobile	67
Leland Stanford Junior University Medical School*	3
University of California Medical School, San Francisco	3
University of Colorado School of Medicine, Boulder	1
Yale University School of Medicine, New Haven, Conn.	2
Hahnemann Medical College and Hospital of Chicago	6
Loyola University School of Medicine, Chicago	3
Rush Medical College, Chicago	7
University of Illinois College of Medicine, Chicago	7
Indiana University School of Medicine, Indianapolis	12
State University of Iowa College of Medicine	1
University of Kansas School of Medicine	17
Johns Hopkins University Medical Department, Baltimore	6
University of Maryland School of Medicine, Baltimore	6
Harvard Medical School, Boston	30
Boston University School of Medicine	50
Detroit College of Medicine and Surgery	8
Washington University Medical School, St. Louis	4
Dartmouth Medical School, Hanover, N. H.	2
University of Buffalo Department of Medicine	1
University of Cincinnati College of Medicine	12
Western Reserve University School of Medicine, Cleveland	1
University of Oregon Department of Medicine, Portland	3
Hahnemann Medical College and Hospital of Philadelphia	12
Jefferson Medical College of Philadelphia	1
Temple University Department of Medicine, Philadelphia	3
University of Pennsylvania School of Medicine, Philadelphia	3
Woman's Medical College of Pennsylvania, Philadelphia	15
Medical College of the State of South Carolina, Charleston	8
University of Tennessee College of Medicine, Memphis	6
Vanderbilt University Medical Department, Nashville, Tenn.	4
Baylor University College of Medicine, Dallas, Tex.	5
University of Texas Department of Medicine, Galveston	1
University of Wisconsin Medical School	6
University of Vermont College of Medicine	1
Medical College of Virginia, Richmond	15
University of Virginia Department of Medicine, Charlottesville	2
Total in 37 medical schools	334

*Have loan funds also.

6. For the standing of these and other medical colleges before state licensing boards, see Table D, THE JOURNAL A. M. A., April 19, 1919, p. 1148.

This college is an off-shoot of the Eclectic Medical University; it has refused to have an inspection made. It is reported not recognized by the Missouri State Board of Health and by the licensing boards of 32 other states.

8. This college was formerly the Central College of Osteopathy; in 1911 it assumed the title Central College Medical Department, and took its present name in 1918.

Loan Funds

Besides the twenty-one colleges marked by an asterisk (*) in the above list which have loan funds for deserving but needy students, such funds are available also at the five following medical schools:

College of Medical Evangelists, Loma Linda, Calif.
Tulane University of Louisiana School of Medicine, New Orleans, La.
University of Missouri School of Medicine, Columbia, Mo.
University of Nebraska College of Medicine, Omaha, Neb.
Wake Forest College School of Medicine, Wake Forest, N. C.
University of North Dakota, School of Medicine, University, N. D.

Hospital Intern Year

Eight medical colleges have adopted the requirement of a fifth year to be spent by the student as an intern in an approved hospital or in other acceptable clinical work before the M.D. degree will be granted. These colleges and the years when the requirement became effective for matriculants and graduates are as follows:

	Affects Matriculants	Affects Graduates
University of Minnesota Medical School	1910-11	1915
Leland Stanford Junior Univ. School of Med.	1914-15	1919
Rush Medical College (University of Chicago)	1914-15	1919
University of California Medical School	1914-15	1919
Northwestern University Medical School	1915-16	1920
University of Vermont College of Medicine	1915-16	1920
Coll. of Phys. and Surg., Los Angeles	1918-19	1923
Columbia Univ. Coll. of Phys. & Surg., New York	1918-19	1923

The hospital intern year has been adopted as an essential qualification for the license to practice in nine states, becoming effective in different years, as follows:

State Board of	Affects Student Matriculants	Affects All Applicants
Pennsylvania	1909-10	1914
New Jersey	1911-12	1916
Alaska	1913-13	1917
Rhode Island	1913-14	1917
North Dakota	1913-14	1918
Washington	1914-15	1919
Illinois	1917-18	1922
Michigan	1917-18	1922
Iowa	1918-19	1923

Laval University Faculty of Medicine.....Quebec, Que.

The University of Alberta at Edmonton, besides the pre-medical year, gives only the first two years of the medical course as measured by that of the medical schools of the United States. It has not been inspected.

DESCRIPTION OF MEDICAL COLLEGES

Below are given brief descriptions of the medical colleges in the United States and Canada that are legally chartered to teach medicine, several of which do not grant degrees. The name, address, year of organization, history and date when first class graduated are given in each instance. Unless otherwise stated, a class graduated each subsequent year. Where official reports have been received from the college, information regarding faculty, entrance requirements, length of term, fees, students (excluding specials and postgraduates), graduates, name of dean and next session is given without discrimination, regardless as to whether the college is sectarian or not. In a few instances in which such reports were not received, the information published is from other reliable sources. Figures for graduates include all who graduated since July 1, 1918. Extracts of rules and the membership of the Association of American Medical Colleges are shown following the list of colleges. Figures showing population of cities and states are taken from the United States Census Bureau's estimate for 1916. Statements have been added showing the preliminary requirements held by state licensing boards where those requirements include one or two years of collegiate work. Nine states, Alaska (Ter.), Illinois, Iowa, Michigan, New Jersey, North Dakota, Pennsylvania, Rhode Island and Washington, require a year's hospital internship before a license will be granted.

ALABAMA

Alabama, population 2,348,273, has one medical college, the School of Medicine of the University of Alabama, located in Mobile, a city with a population of 58,221.

25. Formerly the Central College of Osteopathy; in 1917 under an amended charter took the name of Central College Medical Department; assumed present title in 1918. Rated in Class C March 15, 1918.

26. An offshoot of this institution—the Kansas City College of Medicine and Surgery—was organized in 1915. It is reported not recognized by the Missouri State Board of Health. Since it is an offshoot of a Class C institution reported not recognized by the Missouri State Board of Health, no higher rating could be granted it pending an inspection which it has refused.

27. Rating dropped to Class C July 1, 1909. In 1913 it merged with the Medical Department of the National University of Arts and Sciences, but in 1917 was reestablished. In 1918 reported not recognized by the Missouri State Board of Health.

28. Formerly known as the Cotner University Medical College. Reported suspended in 1918.

29. Rating dropped to Class C Feb. 6, 1916; restored to Class B Feb. 3, 1918.

30. Rating raised to Class B Feb. 4, 1917.

In order to secure licenses to practice medicine in Alabama, students matriculating in the session of 1915-16 and thereafter must have completed two years of work in an approved college of liberal arts, including courses in physics, chemistry, biology and a modern language, prior to entering on the study of medicine. This applies to all graduates of 1919 and thereafter.

Mobile

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE, 550 St. Anthony Street—Organized in 1859 as the Medical College of Alabama. Classes were graduated in 1861 and in all subsequent years except 1862 to 1868 inclusive. It was reorganized as the Medical Department of the University of Alabama in 1897. All property was transferred to the University of Alabama in 1907 when the present title was assumed. Two years of college work are required for admission. The faculty consists of 20 professors and 25 lecturers and assistants, a total of 45. The course of study covers four years of thirty-two weeks each. The total fees for each of the four years, respectively, are \$165, \$160, \$160 and \$185. The Dean is Dr. T. H. Frazer. The total registration for 1918-1919 was 56; graduates, 4. The fifty-fourth session begins Oct. 3, 1919, and ends June 4, 1920.

ARKANSAS

Arkansas, population 1,753,033, has one medical college, the Medical Department of the University of Arkansas, located in Little Rock, a city of 57,343. Hereafter it offers only the courses of the first two years of the medical course.

To secure licenses to practice medicine in Arkansas, students matriculating in the session of 1918-19 and thereafter must have completed two years of collegiate work, including college courses in physics, chemistry, biology and a modern language before beginning the study of medicine. This applies to all graduates of 1922 and thereafter.

Little Rock

UNIVERSITY OF ARKANSAS MEDICAL DEPARTMENT, Markham and Center Streets—Organized in 1879 as the Medical Department of Arkansas Industrial University. It assumed the present title in 1899. In 1911 the College of Physicians and Surgeons united with it and the new school was made an integral part of the University of Arkansas. The first class was graduated in 1890. The faculty consists of 39 professors and 36 lecturers and assistants, total 56. Entrance requirements are two years of collegiate work beyond a fourth year high school course. The course of study covers two years of thirty-two weeks each. The fees are \$50 each year. The Dean is Dr. Morgan Smith. Total registration 1918-1919 was 43; graduates, 7. The forty-first session begins Sept. 22, 1919, and ends June 9, 1920.

CALIFORNIA

California, population 2,983,843, has four medical colleges. Two are located in San Francisco, a city of 463,516 inhabitants. They are Leland Stanford Junior University School of Medicine and the College of Medicine of the University of California. The College of Physicians and Surgeons, Medical Department of the University of Southern California is situated in Los Angeles, population 503,812. The College of Medical Evangelists is located at Loma Linda and Los Angeles.

To secure licenses to practice medicine in California under the "physician's and surgeon's" certificate, students matriculating in medical colleges in and after the session of 1915-16, prior to such matriculation, must have completed at least one year of recognized collegiate work including college courses in physics, chemistry, biology and a modern language. This applies to all graduates of 1919 and thereafter.

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, UNIVERSITY CAMPUS, Berkeley; Second and Pattee Streets, San Francisco—Organized in 1863 as the Toland Medical College. The first class graduated in 1864. In 1872 it became the Medical Department of the University of California. In 1909 the College of Medicine of the University of Southern California, at Los Angeles, by legislative enactment, became a clinical department. This Los Angeles portion was changed to a graduate school in 1914. In 1915 the Halphen Medical College of the Pacific was merged, and elective chairs in homeopathic materia medica and therapeutics were provided for. Two years of collegiate work are required for admission. The work of the first year and a half is given at Berkeley and the work of the last two and a half years at San Francisco. The faculty is composed of 12 professors and 18 associates and assistants, a total of 40. The course covers five years of nine months each, the fifth year to consist of an internship or of special work in a department of the medical school. Fees for the four years, respectively, are \$200, \$155, \$150 and \$150. The Dean is Dr. Herbert C. Moffit, San Francisco. Total registration for 1918-1919 was 188; graduates, 22. The forty-seventh session begins Aug. 19, 1919, and ends May 12, 1920.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS.—Organized in 1909. The faculty numbers 87. The first class graduated in 1914. The laboratory departments are at Loma Linda; the clinical departments at Los Angeles. The course extends over four years of nine months each. Two years of college work are required for admission. The total fees for the four years, respectively, are \$181, \$181, \$176, and \$186. The Dean is Dr. P. T. Magan. The total registration for 1918-1919 was 84; graduates, 5. The eleventh session begins Sept. 7, 1919, and ends June 3, 1920.

Los Angeles

COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT OF THE UNIVERSITY OF SOUTHERN CALIFORNIA, 516 East Washington Street.—Organized in 1903, first class graduated in 1905; became Medical Department, University of Southern California, Aug. 11, 1909. The course covers four years of nine months each. Two years of collegiate work are required for admission. The faculty consists of 22 professors and 77 associate professors, lecturers and instructors, a total of 99. The fees for the four years, respectively, are \$222, \$217, \$202 and \$227. The Dean is Dr. Charles W. Bryson. The registration for 1918-1919 was 81; graduates, 28. The next session begins Sept. 2, 1919, and ends June 17, 1920.

San Francisco-Palo Alto

JELEND STANFORD JUNIOR UNIVERSITY SCHOOL OF MEDICINE, University Campus, Palo Alto, and Sacramento and Webster Streets, San Francisco.—Organized in 1908 when, by an agreement, the interests of Cooper Medical College were taken over. The first class was graduated in 1913. The faculty consists of 43 professors and 52 lecturers, assistants, etc., a total of 95. Three years of collegiate work are required for admission. The school has the quarter system and the completion of any three quarters constitutes a college year. The course covers five years of nine months each, including a year of practical or intern work. The total fees for each of the first four years is \$159. The Dean is Dr. W. Ophuls, San Francisco. The total registration for 1918-1919 was 109; graduates, 16. The tenth session begins Oct. 1, 1919, and ends June 16, 1920.

COLORADO

Colorado, with a population of 975,190, has one medical college, the University of Colorado School of Medicine. The first two years of the course are given at Boulder, the seat of the university, while the last two, or clinical years, are given in Denver, which has a population of 200,800.

The Colorado State Board of Medical Examiners will register without further examination graduates of medical colleges in good standing who present licenses issued after examination by any other licensing board. The law permits any one, graduate or non-graduate, to try the board's written examination. No graduate of 1914 or thereafter is eligible to obtain a license in Colorado, or indorsement of his credentials, unless he graduated from a medical college which, at the time he matriculated, required at least two years' study, without conditions, in an accredited college of liberal arts, and this work must have included courses in physics, chemistry, biology and one modern language.

Boulder-Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911. The faculty embraces 12 professors, 18 associate and assistant professors, and 31 lecturers, instructors and assistants, a total of 61. The work embraces a graded course of four years of nine months each. The entrance requirements are two years of college work counting toward a degree in arts in an accredited college or university. The tuition is \$90 per year for residents of Colorado, \$120 for nonresidents. Laboratory fees are \$10 for each of the first two years. The Dean is Dr. Charles N. Mander. The total registration for 1918-1919 was 75; graduates, 19. The thirty-eighth session begins Sept. 29, 1919, and ends June 11, 1920.

CONNECTICUT

Connecticut, with a population of 1,254,926, has one medical college, Yale University, School of Medicine, located in New Haven, population 149,685.

Candidates for license to practice medicine in Connecticut who graduate in 1914 or thereafter are not eligible unless, prior to entering on the study of medicine, they had completed, in addition to an accredited four-year high school education, at least nine months of collegiate work including college courses in physics, chemistry and general biology.

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 150 York Street and Congress Avenue and Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first

class graduated in 1814. A new charter in 1829 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. The faculty consists of 23 professors and 68 lecturers and assistants, a total of 91. The requirements for admission are two years of collegiate work plus evidence of satisfactory completion of courses in general physics, general inorganic chemistry, general biology, organic chemistry and physical chemistry or laboratory physics, all reasonably equivalent to the courses in these subjects in Yale University. The student also must have a reading knowledge of German. The course covers four years of nine months each. The fees for the four years, respectively, are approximately \$205, \$200, \$200 and \$210. The Dean is Dr. George Blumer. The total registration for 1918-1919 was 69; graduates, 12. The one hundred and seventh session begins Sept. 5, 1919, and ends June 23, 1920.

DISTRICT OF COLUMBIA

The District of Columbia, population 366,631, has three medical colleges; George Washington University Medical School, Georgetown University, School of Medicine and Howard University, School of Medicine.

Washington

GEORGE WASHINGTON UNIVERSITY MEDICAL SCHOOL, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years, except 1831 to 1838, and 1901 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an act of Congress, the title of George Washington University was granted to the institution. The faculty is composed of 38 professors and 55 instructors, demonstrators and assistants, a total of 93. Two years of collegiate work are required for admission. The course covers four years of thirty-two weeks each. The total fees are \$175 each year. The Dean is Dr. William C. Borden. The total registration for 1918-1919 was 101; graduates, 16. The ninety-eighth session begins Sept. 24, 1919, and ends June 2, 1920.

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 920 H Street, N.W.—Organized in 1851. The first class graduated in 1852. The faculty contains 25 professors, 67 instructors and assistants; total, 92. Two years of collegiate work are required for entrance. The course of study covers four terms of eight and one-half months each. The fees for the first year are \$190, and for each of the other three years, \$175. The Dean is Dr. George M. Kober. The registration for 1918-1919 was 73; graduates, 8. The sixty-ninth session begins Sept. 26, 1919, and ends June 11, 1920.

HOWARD UNIVERSITY SCHOOL OF MEDICINE, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1874. Colored students compose a majority of those in attendance. The faculty comprises 16 professors and 24 lecturers and assistants, 40 in all. The admission requirements are two years of collegiate work, including physics, chemistry, botany and zoology, English and two years of French or German. The course covers four years of thirty-two weeks each. The fees of each of the four sessions, respectively, are \$165, \$155, \$155 and \$162. The Dean is Dr. Edward A. Balloch. Registration for 1918-1919 was 108; graduates, 21. The fifty-second session begins Oct. 1, 1919, and ends June 11, 1920.

GEORGIA

Georgia, population 2,875,953, has two medical colleges. University of Georgia, Medical Department, located in Augusta, population 50,245, and the Emory University School of Medicine in Atlanta, a city of 190,558.

In order to secure a license to practice medicine in Georgia, students matriculating in the session of 1918-19 and thereafter must have completed two years of work in an approved college of liberal arts and sciences, including courses in physics, chemistry and biology, prior to entering on the study of medicine. This applies to all graduates of 1922 and thereafter.

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 94 N. Butler Street.—Organized in 1854. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), re-assuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915; assumed present title in 1917. Two years of collegiate work are required for entrance. The faculty numbers 106. The course of study is four years of thirty-two weeks each. The fees for each of the four years, respectively, are \$175, \$160, \$155 and \$180. The Dean is Dr. W. S. Elkin. Total registration for 1918-1919 was 147; graduates, 25. The next session begins Sept. 30, 1919, and ends June 8, 1920.

Augusta

UNIVERSITY OF GEORGIA, MEDICAL DEPARTMENT, University Place.—Organized in 1838 as the Medical Academy of Georgia, the name being

changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia. Entire property transferred to the university in 1911. Classes were graduated in 1833 and in all subsequent years except 1862 and 1863. The faculty includes 19 professors and 30 assistants, 48 in all. Two years of collegiate work are required for entrance. The course is four years of thirty-four weeks each. Fees are \$5 for matriculation and \$60 each year for residents of Georgia and \$150 each year for non-residents. The Dean is Dr. W. H. Doughty, Jr. The total registration for 1918-1919 was 63; graduates, 8. The eighty-eighth session begins Sept. 12, 1919, and ends May 29, 1920.

ILLINOIS

Illinois, population 6,193,626, has six medical colleges, two of which give instruction at night, all located in Chicago, a city of 2,497,722 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, University of Illinois College of Medicine, Hahnemann Medical College and Hospital, Loyola University School of Medicine and the Chicago Hospital College of Medicine.

To be eligible for license to practice medicine in Illinois, students matriculating in the sessions of 1915-16 and of 1918-19, in addition to an accredited four-year high school education, must have completed, respectively, one year and two years of collegiate work including courses in physics, chemistry, biology and a modern language, to be taken either in a preliminary year given by a recognized medical college, or in an approved college of liberal arts. Graduates of 1923 and thereafter must have completed also a year's internship in a hospital.

Chicago

RUSH MEDICAL COLLEGE.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 until 1898, when it became affiliated with the University of Chicago. The first class graduated in 1844. The faculty is composed of 112 professors, 197 associates, instructors, etc., a total of 309. The requirements for admission are two years of college work, including courses in college chemistry, physics and biology, and a reading knowledge of German or French. Classes are limited to 100 students in each of the freshman and sophomore classes, and to 120 students in each of the clinical years. No application for admission is accepted after September 1. The school operates under the "quarter system" in which the year is divided into four quarters of twelve weeks each; the completion of the work of three of these quarters gives credit for a college year. The course covers four years of eight and a half months each, and a fifth year, consisting of a hospital internship or of a fellowship in one of the departments. All freshman and sophomore studies are given at the University of Chicago. The clinical years are given in the building at the corner of Wood and Harrison streets. The tuition fees for each of the first four years, respectively, are \$195, \$190, \$180 and \$195. A matriculation fee of \$5 is paid but once, and there are incidentals amounting to from \$5 to \$7 annually. The Deans are Dr. Frank Billings and Dr. John M. Dalsion. Total registration 1918-1919 632; graduates, 76. One hundred and twenty-two other students completed the work of the fourth year but will not receive their degrees till the hospital internship has been completed. The seventy-sixth session begins Oct. 1, 1919, and ends June 19, 1920.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 2421 South Dearborn Street.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869, but retained the name of Chicago Medical College until 1891, when the present name was taken. Became an integral part of Northwestern University in 1905. The faculty comprises 62 professors and 94 lecturers and assistants, a total of 156. The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University, plus two years of college work, including courses in physics, chemistry, biology and a modern language. The course covers four years of eight months each. The fees for the four years, respectively, are \$205, \$200, \$195 and \$210. The Dean is Dr. Arthur I. Kendall. The total registration for 1918-1919 was 294; graduates, 19. The sixtieth session begins Oct. 7, 1919, and ends June 13, 1920.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, Honore and Congress Streets.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897 and an integral part in 1913. The relationship with the university was canceled in June, 1912, but restored in March, 1913, when the present title was assumed. Two years of collegiate work are required for admission. The year is divided into three divisions of four months each, the completion of the work of any two divisions counting as a college year. The faculty is composed of 42 professors, 73 assistants and instructors, a total of 115. The total fees for the four years, respectively, are \$165, \$160, \$150 and \$165. The Dean is Dr. Albert C. Eycleshymer. The total registration for 1918-1919 was 264; graduates, 45. The thirty-eighth session begins Oct. 1, 1919, and ends June 5, 1920.

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 S. Lincoln St., Chicago.—Organized in 1868 as the Bennett College of Eclectic Medicine and Surgery. Eclecticism dropped and title of Bennett Medical College assumed in 1909. First class graduated in 1870, and a class graduated each subsequent year. Absorbed the Illinois Medical College in 1910

and the Reliance Medical College in 1911. In 1910 it became by affiliation the School of Medicine of Loyola University; the university assumed full control in 1915. Took over by purchase the Chicago College of Medicine and Surgery in 1917. Two years of college work are required for admission. The faculty is composed of 72 professors, 62 assistants and instructors, a total of 134. The total fees for the four years are, respectively, \$166, \$166, \$166 and \$211. The Dean is Dr. Lawrence Ryan. The total enrollment for 1918-1919 was 271; graduates, 72. The next session begins Oct. 1, 1919, and ends June 12, 1920.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF CHICAGO, 2841 Cottage Grove Avenue.—Organized in 1859. The first class was graduated in 1861. Absorbed the Chicago Homeopathic Medical College in 1904. The faculty includes 59 professors and 27 lecturers, assistants, etc., a total of 86. Two years of collegiate work are required for admission. The course extends over four years of eight months each. The tuition fees for the four years, respectively, are \$176, \$161.50, \$176.50 and \$191.50. The Dean is Dr. Joseph P. Cobb. The total registration for 1918-1919 was 42; graduates, 20. The sixtieth session begins Sept. 29, 1919, and ends June 10, 1920.

CHICAGO HOSPITAL COLLEGE OF MEDICINE, an afternoon and night school, located at 3832 Rhodes Avenue.—Organized in 1911; chartered in 1912. In December, 1917, the classes of the Jenner Medical College were transferred to it. Total registration for 1918-1919 was 34; graduates, about 12. Official reports indicate that the diplomas from this college are not recognized by the licensing boards of thirty-seven states.

INDIANA

Indiana, population 2,826,154, has one medical college, the Indiana University School of Medicine, located at Indianapolis, a city of 271,708 people, except that the work of the first year is offered also at Bloomington, the seat of the University.

Candidates for license to practice medicine in Indiana who matriculated between Jan. 11, 1910, and Jan. 1, 1911, must have completed one year of collegiate work, in addition to an accredited four-year high school course, prior to beginning the study of medicine. Those matriculating subsequent to Jan. 1, 1911, must have completed two years of work in a recognized college of liberal arts.

Bloomington and Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE—Organized in 1903, but did not give all of the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879), merged into it. The first class was graduated in 1908. The faculty consists of 71 professors and 85 lecturers, associates and assistants, a total of 156. Two years of collegiate work are required for admission. The work of the first year is emphasized only at Bloomington. The work of the other three years is all at Indianapolis. The fees for the four years, respectively, are \$100, \$100, \$130 and \$130. A fifth optional intern year leading to the "M.D. cum laude" has been added. The Secretary at Bloomington is Dr. E. D. Myers; the Dean is Dr. Charles P. Emerson, Indianapolis. The total registration for 1918-1919 was 200; graduates, 32. The next session begins Sept. 15, 1919, and ends June 9, 1920.

IOWA

Iowa, population 2,224,771, has one medical college, the College of Medicine of the State University of Iowa, located in Iowa City, population 12,033.

Candidates for license to practice medicine in Iowa who graduated subsequent to Jan. 1, 1915, must have completed two years of work in an approved college of liberal arts prior to beginning the study of medicine, this preliminary college work to have included courses in physics, chemistry, biology and a foreign language.

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus.—Organized in 1869. First session began in 1-70. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. The faculty is made up of 25 professors, 10 lecturers, demonstrators and assistants, a total of 41. Two years of collegiate work, including courses in physics, chemistry, biology and French or German, are required for admission. The course of study covers four years of thirty-six weeks each. The tuition fee for residents of Iowa is \$85 per year and for nonresidents \$100, plus a matriculation fee of \$10 and a graduation fee of \$10. The Dean is Dr. Lee W. Allen, Iowa City. Total registration for 1918-1919 was 238; graduates, 44. The fiftieth session begins Sept. 29, 1919, and ends June 11, 1920.

KANSAS

Kansas, population 1,840,707, has one medical college. The School of Medicine of the University of Kansas gives its first two years in Lawrence, population 12,915, and the last two

years in Rosedale, a suburb of the two Kansas Cities, which together have a population of 397,284.

Candidates for license to practice medicine in Kansas who matriculated in the session of 1910-11 and thereafter must present credentials showing that they matriculated in and graduated from a medical college which required for admission at least one year of collegiate work including college courses in physics, chemistry and biology in addition to an accredited four-year high school course. This applies to graduates of 1914 and thereafter. Students matriculating in 1918-19 (graduates of 1922) and thereafter will be required to have completed two years of premedical college work.

Lawrence and Rosedale

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE.—Organized in 1880. It offered only the first two years of the medical course until in 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medical-Chiropractic College, founded in 1897. First class graduated in 1906. The clinical courses are given at Rosedale. Absorbed Kansas Medical College in 1913. The faculty, including lecturers and clinical assistants, numbers 70. The requirements for admission are two years of collegiate work. The course covers four years of nine months each. The total fees are, \$100 for each year. The Dean is Dr. S. J. Crumrine; Associate Dean, Dr. M. T. Sudler. The total registration for 1918-1919 was 116; graduates, 20. The fortieth session begins Sept. 15, 1919, and ends June 9, 1920.

KENTUCKY

Kentucky, population 2,386,866, has one medical college, the University of Louisville Medical Department, situated in Louisville, a city of 238,910 inhabitants.

To be eligible for license to practice medicine in Kentucky, all students matriculating in and after the session of 1914-15 and 1918-19, in addition to an accredited four-year high school course, must have completed, respectively, one year and two years of college work, including college courses in physics, chemistry, biology and a modern language prior to beginning the study of medicine.

Louisville

UNIVERSITY OF LOUISVILLE MEDICAL DEPARTMENT. First and Chestnut Streets.—Organized in 1837 as the Louisville Medical Institute. The first class graduated in 1838, and a class graduated in each subsequent year except in 1863. In 1846 the present name was assumed. In 1907 it absorbed the Kentucky University Medical Department. In 1908 it absorbed the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. One year of collegiate work is required for admission. It has a faculty of 29 professors and 80 lecturers and assistants, a total of 109. The course covers four years of thirty-two weeks each. The fees for each of the four years, respectively, are \$175, \$176, \$179.25 and \$182.35. The Dean is Dr. Henry Enos Tuley. The total registration for 1918-1919 was 99; graduates, 18. The next session begins Sept. 23, 1919, and ends June 5, 1920.

LOUISIANA

Louisiana, having a population of 1,843,042, contains one medical college, the School of Medicine of the Tulane University of Louisiana, situated in New Orleans, a city of 371,747.

Candidates for license to practice medicine in Louisiana who graduate in 1919 and 1922 must present evidence that they have successfully completed, at an approved college or university, respectively, one year and two years of college work including biology, physics, chemistry and a modern language, before entering on the study of medicine. These requirements apply to all students who matriculated, respectively, in 1915 and 1918.

New Orleans

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE. University Campus and 1511 Canal Street.—Organized in 1835 as the Medical College of Louisiana. Classes were graduated in 1836 and in all subsequent years except 1867-68, inclusive. It was transferred to the Medical Department of the University of Louisiana in 1847 and became the Medical Department of the Tulane University of Louisiana in 1884. Present name in 1913, when it became the School of Medicine of the College of Medicine of the Tulane University of Louisiana. The faculty has 53 professors and 86 assistant professors, instructors, demonstrators, etc., a total of 139. The course covers four years of thirty-two weeks each. Two years of collegiate work are required for admission. Total fees for each of the four years, respectively, are \$300, \$300, \$305 and \$335. The Dean is Dr. Isador Dietz. The total registration for 1918-1919 was 275; graduates, 73. The eighty-fifth session begins Sept. 22, 1919, and ends June 9, 1920.

MAINE

Maine, population 774,914, has one medical college, the Bowdoin Medical School, located in Brunswick and Portland, the latter having a population of 68,867.

To secure a license to practice in Maine students matriculating in and after the session of 1915-16 must have completed one year of work in an approved college of arts and sciences before entering on the study of medicine. This applies to graduates of 1919 and thereafter.

Brunswick-Portland

BOWDOIN MEDICAL SCHOOL. The Medical Department of Bowdoin College. The first two years are given at Bowdoin College, Brunswick, the last two at Portland, building located on Chadway Street. Organized in 1820 as the Medical School of Maine. The first class graduated in 1821. Present title assumed in 1915. The faculty numbers 58. Two years of collegiate work, including courses in physics, chemistry and biology are required for admission. The course covers four years of eight months each. The total fees for each of the four years, respectively, are \$130, \$126, \$110 and \$105. The Dean is Dr. Addison S. Thayer, 10 Deering Street, Portland. The total number of students in 1918-1919 was 45; graduates, 16. The ninety-ninth session begins Oct. 9, 1919, and ends June 21, 1920.

MARYLAND

Maryland, with a population of 1,368,240, contains two medical colleges, located in Baltimore, a city with 589,621 inhabitants. They are as follows: Johns Hopkins University Medical Department, and the University of Maryland School of Medicine and College of Physicians and Surgeons, the last two having been merged.

To be eligible to practice medicine in Maryland, all students matriculating in the session of 1914-15 and 1918-19, in addition to a four-year high school education, must have completed, respectively, one year and two years of college work including courses in physics, chemistry, biology and French or German, prior to beginning the study of medicine.

Baltimore

JOHNS HOPKINS UNIVERSITY MEDICAL DEPARTMENT. Washington and Monument Streets.—Organized in 1893. The first class graduated in 1897. The faculty consists of 30 professors and 131 clinical professors, etc., a total of 181. The requirements for admission demand that the applicant either has (a) completed the chemical-biologic course which leads to the A.B. degree in the university, or (b) graduated at an approved college or scientific school and has a knowledge of French and German, physics, chemistry and biology, such as may be obtained from a year's course. The course extends over four years of eight and one-half months each. The total fees are \$267 each year. The Dean is Dr. J. Whitridge Williams. Total registration for 1918-1919 was 374; graduates, 93. The twenty-seventh session begins Sept. 30, 1919, and ends June 15, 1920.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND THE COLLEGE OF PHYSICIANS AND SURGEONS. Lombard and Green Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged into it in 1913. In 1913 the College of Physicians and Surgeons was merged and the present name assumed. The combined faculty numbers 173. Two years of collegiate work are required for admission. The course covers four years of eight months each. The total fees are \$205 each year; The Dean is Dr. J. M. H. Rowland. Total registration for 1918-1919 was 235; graduates, 50. The thirteenth session begins Oct. 1, 1919, and ends June 1, 1920.

MASSACHUSETTS

Massachusetts, population 3,747,564, has five medical colleges: Medical School of Harvard University, Boston University School of Medicine, Tufts College Medical School, College of Physicians and Surgeons and the Middlesex College of Medicine and Surgery. They are all situated in Boston, a city of 750,476, except the last named which is in Cambridge.

Boston

MEDICAL SCHOOL OF HARVARD UNIVERSITY. 240 Longwood Avenue.—Organized in 1782. The first class graduated in 1788. It has a faculty of 63 professors and 206 instructors and assistants, a total of 269. Candidates for admission must present a college degree or two years of work leading to such a degree with standing in the upper third of the class. The college work must include a year of physics, biology, general chemistry, a half year of organic chemistry, and a reading knowledge of French or German. The total fees for each of the four years are \$230, \$225, \$225 and \$235. The Dean is Dr. David L. Edsall. The total registration for 1918-1919 was 399; graduates 98. The one hundred and thirty-eighth session begins Sept. 22, 1919, and ends May 29, 1920.

BOSTON UNIVERSITY SCHOOL OF MEDICINE. 80 East Concord Street.—Organized in 1873. In 1874 the New England Female Medical College,

founded in 1848, was merged into it. The first class graduated in 1871. Became nonsectarian in 1918. Two years of collegiate work are required for admission. The faculty includes 25 professors, 54 associates, etc., making a total of 79. The course covers four years of eight months each. Total fees for each of the four years, respectively, are \$182.50, \$169.50, \$167.50, \$190. The Dean is Dr. John P. Sutherland. Total registration for 1918-1919 was 60; graduates, 15. The forty-seventh session begins Oct. 2, 1919, and ends June 2, 1920.

TUFTS COLLEGE MEDICAL SCHOOL, 46 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. It has a faculty of 42 professors and 61 assistants, lecturers, etc., a total of 103. Two years of collegiate work is required for admission. The course covers four years of eight months each. The total fees for each of the four years are \$177.50, \$169, \$155 and \$155. The Dean is Dr. Charles F. Painter. Total registration for 1918-1919 was 358; graduates, 92. The twenty-fourth session begins Sept. 22, 1919, and ends June 15, 1920.

COLLEGE OF PHYSICIANS AND SURGEONS, 517 Shawmut Avenue.—Organized in 1886. The first class graduated in 1887. Total attendance of medical students during 1918-1919 was about 35. There were no graduates. This college has been reported not recognized by the Massachusetts Medical Society and by the licensing boards of thirty states.

Cambridge

MIDDLESEX COLLEGE OF MEDICINE AND SURGERY, Cambridge.—Organized in 1914 under the charter of the Worcester Medical College, which became extinct in 1859. A class was graduated in 1915 and each subsequent year. Was closely related in its interests with an osteopathic college and granted a liberal advanced standing for work done in that and other osteopathic colleges. During 1918-1919 it had a total enrollment of about 77; graduates, 10. This college has been reported as not recognized by the licensing boards of thirty-six states.

MICHIGAN

Michigan, population 3,074,560, has three medical colleges. Two of these, the University of Michigan Department of Medicine and Surgery and the Homeopathic Medical College of the University of Michigan, are located at Ann Arbor, a city of 14,979 people. The Detroit College of Medicine and Surgery is located at Detroit, a city of 571,784 inhabitants.

To be eligible for license to practice medicine in Michigan, all students matriculating in and after the sessions of 1914-15 and 1918-19, in addition to an accredited four-year high school education, must have completed, respectively, one year and two years of work in an approved college of liberal arts, including college courses in physics, chemistry, biology and French or German, prior to beginning the study of medicine.

Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. It has a faculty composed of 18 professors and 88 associates, instructors, etc., a total of 106. The entrance requirements are two years of college work, including courses in chemistry, physics and biology, with laboratory work, and a reading knowledge of one modern language. The curriculum embraces four years of nine months each. The total fees for Michigan students are \$105 each year and \$125 for nonresidents. The Dean is Dr. Victor C. Vaughan. The total registration for 1918-1919 was 361; graduates, 54. The seventeenth session begins Sept. 30, 1919, and ends June 24, 1920.

UNIVERSITY OF MICHIGAN HOMOEOPATHIC MEDICAL SCHOOL.—Organized in 1875. The first class graduated in 1877. The work of the first two years is taken under the same teachers and in the same classes with the Medical School of the University of Michigan, and the fees charged are the same. The faculty of the last two years comprises 9 professors and 11 associates, instructors, etc. The entrance requirements are two years of collegiate work. The Dean is Dr. W. H. Hinsdale. The total registration for 1918-1919 was 31; graduates, 11. The next session begins Sept. 30, 1919, and ends June 24, 1920.

Detroit

DETROIT COLLEGE OF MEDICINE AND SURGERY, 250 St. Antoine Street.—Organized as the Detroit College of Medicine in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. Reorganized with present title in 1913. The first class graduated in 1886. In 1918 it became a nominal institution under the control of the Detroit Board of Education. Entrance requirements are two years of collegiate work. The faculty embraces 27 professors, 123 lecturers, etc., a total of 150. The course covers four years of eight months each. The fees for the four years, respectively, are \$135, \$150, \$150 and \$180. The Dean is Dr. W. H. MacCracken. The total registration for 1918-1919 was 134; graduates, 29. The thirty-fifth session begins Oct. 6, 1919, and ends June 26, 1920.

MINNESOTA

Minnesota, population 2,296,024, contains one medical school, the University of Minnesota Medical School, situated in Minneapolis, a city of 363,454 inhabitants.

Candidates for license to practice medicine in Minnesota who graduated subsequent to June 1, 1912, in addition to an accredited four-year high school education, must have completed two years of work the equivalent of that done in the liberal arts department of the University of Minnesota, including courses in physics, chemistry and biology, prior to beginning the study of medicine.

Minneapolis

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. The faculty includes 76 professors and 107 instructors and assistants, a total of 183. The curriculum covers four years of nine months each and a year's internship in an approved hospital. The entrance requirements are two years of university work, which must include one year each of physics, general chemistry, qualitative analysis, zoology or botany, and French or German, all in addition to a four-year high school course, including two years of Latin. Students entering hereafter will be required to secure a degree of B.S. or A.B. before the M.D. is granted. Total fees are \$150 each year. The Dean is Dr. E. P. Lyon. The total registration for 1918-1919 was 280; graduates, 54. The thirty-first session begins Oct. 1, 1919, and ends June 17, 1920.

MISSISSIPPI

Mississippi, population 1,964,122, has one medical college, the Department of Medicine of the University of Mississippi, which is located at Oxford, a city of 2,014 inhabitants.

Candidates for license to practice medicine in Mississippi who matriculate in the sessions of 1915-16 and of 1919-20 and thereafter, in addition to a standard four-year high school education, must have completed, respectively, one year and two years of work in an approved college or university, including courses in physics, chemistry, biology and a modern language, before entering on the study of medicine.

Oxford

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE.—Organized in 1903. Gives only the first two years of the medical course. In 1908 a clinical department was established at Vicksburg, but was discontinued in 1910 after graduating one class. The session extends over eight and a half months. Entrance requirements are two years of college work. The total fees each year are \$122. The faculty numbers 18. The Dean is Dr. W. S. Leathers. The total registration for 1918-1919 was 48. The seventeenth session begins Sept. 17, 1919, and ends June 1, 1920.

MISSOURI

Missouri, population 3,420,143, has six medical colleges. St. Louis, population 757,309, contains three of these, viz., the School of Medicine of St. Louis University, Washington University Medical School, and the St. Louis College of Physicians and Surgeons. Kansas City, with a population of 297,847, has two colleges, the Kansas City College of Medicine and Surgery and the Kansas City University of Physicians and Surgeons. The School of Medicine of the University of Missouri is at Columbia, a town of 12,103 people.

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE.—Organized at St. Louis in 1814, was discontinued in 1855, but was reorganized at Columbia in 1872. Teaching of the clinical cases was suspended in 1909. The faculty includes 9 professors and 10 assistant professors, lecturers, etc., a total of 25. The course covers two years of nine months each. The entrance requirements are two years of college work including French or German, 8 hours; general zoology, 8 hours; physics, 8 hours; inorganic chemistry, 8 hours, and general botany, 3 hours. Total fees are \$80 for the first and \$51 for the second year. The Dean is Dr. Guy L. Noyes. Total registration for 1918-1919 was 65. The next session begins Aug. 29, 1919, and ends April 22, 1920.

Kansas City

KANSAS CITY COLLEGE OF MEDICINE AND SURGERY, Eclectic, Twenty-Third and Holmes Streets.—Organized in 1915 as an offshoot of the Eclectic Medical University, a Class C medical school, now extinct. Total registration for 1918-1919 was about 97; graduates, 34. Since this school is an offshoot of a Class C medical college and is reported not recognized by the Missouri State Board of Health and by the licensing boards of thirty-two other states, no higher rating can be granted to it, pending an inspection which it has refused.

KANSAS CITY UNIVERSITY OF PHYSICIANS AND SURGEONS, 729 Tenth Street.—Originally chartered in 1903 as the Central College of Osteopathy, charter amended in 1917, by which it obtained the right to grant degrees in medicine, and the name was changed to the Central College Medical Department. Present title in 1918. Very liberal in awarding standing allowed for work done in osteopathic colleges. There were 129

medical students enrolled in 1918-1919, of whom 75 graduated. Rated in Class C by the Council on Medical Education. Reported not recognized by the licensing boards of Missouri and of thirty-three other states.

St. Louis

WASHINGTON UNIVERSITY MEDICAL SCHOOL, Kingshighway and Euclid Avenue.—Organized in 1842 as the Medical Department of St. Louis University. In 1845 it was chartered as an independent institution under the name of St. Louis Medical College. The first class graduated in 1845. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. The faculty comprises 31 professors and 83 lecturers, instructors, etc., a total of 114. Two full years of college work are required for admission, including courses in English, physics, chemistry and biology and a reading knowledge of German. The course is four years of eight months each. The total fees for the four years are, respectively, \$205, \$200, \$200 and \$205. The Dean is Dr. C. Canby Robinson. The total registration for 1918-1919 was 156; graduates, 50. The next session begins Sept. 25, 1919, and ends June 10, 1920.

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, 1402 South Grand Avenue.—Organized in 1890 as the Marion Sims Beaumont Medical College by union of Marion Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical Department of St. Louis University in 1903. The faculty is composed of 47 professors, 80 lecturers and assistants, a total of 127. One year of college subjects preliminary to the four years of medical subjects is given in the medical school. Two years of collegiate work are required for admission. The curriculum covers four years of thirty-two weeks each. Summer semester optional. The total fees are \$175 each year. The Dean is Dr. Hanau W. Loeb. The total registration for 1918-1919 was 253; graduates, 49. The next session begins Oct. 1, 1919, and ends May 31, 1920.

ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS, Jefferson and Gamble Streets.—Organized in 1869. Classes graduated in 1870 and each subsequent year until 1873, when it suspended. Reorganized in 1879. Classes graduated in 1880 and subsequent years until 1913, when it merged with the Medical Department of the National University of Arts and Sciences. Reestablished in 1916. The Dean is Dr. Waldo Bridges. Registration during 1918-1919, 32; graduates, 24. The next session begins Oct. 1, 1919, and ends June 3, 1920. This college is reported as not recognized by the licensing boards of Missouri and thirty-seven other states.

NEBRASKA

Nebraska, population 1,277,750, has two medical colleges. The University of Nebraska College of Medicine and the John A. Creighton Medical College of Omaha, population 165,470.

Omaha

JOHN A. CREIGHTON MEDICAL COLLEGE, Fourteenth and Davenport Streets.—It is the Medical Department of Creighton University. Organized in 1892. The first class graduated in 1893. It has a faculty of 15 professors and 40 associates, lecturers and assistants, a total of 55. Two years of collegiate work are required for admission. The course of study embraces four years of eight months each. Continuous session adopted for seniors only. The total fees each year for the four years are, respectively, \$160, \$156, \$156, and \$161. The Dean is Dr. Herman von W. Schulte. Total registration for 1918-1919 was 92; graduates, 19. The thirty-eighth session begins Sept. 22, 1919, and ends June 5, 1920.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Fifth Second Street and Daway Avenue. Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The first two years were given at Lincoln and the last two in Omaha until 1913, when all four years were transferred to Omaha. The faculty is composed of 22 professors and 46 lecturers and instructors, total 68. Two years of collegiate work are required for admission, including courses in physics, chemistry, zoology and a modern language. The fees for each of the four years, respectively, are \$135, \$130, \$130 and \$120. The Dean is Dr. Irving S. Carter. Total registration for 1918-1919 was 162; graduates, 34. The next session begins Sept. 22, 1919, and ends June 10, 1920.

NEW HAMPSHIRE

New Hampshire, population 443,467, has one medical college, located at Hanover, population 2075.

To be eligible for license to practice medicine in New Hampshire, all students matriculating in and after the session of 1915-16, in addition to a four-year high school education, must have completed at least two years of work in an approved college of liberal arts, prior to beginning the study of medicine.

DARTMOUTH MEDICAL SCHOOL. Organized as New Hampshire Medical Institute in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Clinical teaching was discontinued in 1911. The faculty is made up of 11 professors and 1 instructor, a total of 12. Two years of collegiate work are required for admission. The course covers nine calendar months in each year, or eight months of actual teaching. Candidates for the B.S. degree in

Dartmouth College may substitute the work of the first two years in medicine for that of the junior and senior years in the academic department. Candidates for the A.B. degree may make a similar saving of one year. The fees for each year are \$180. Dean, Dr. John M. Gleason; Secretary, Colin C. Stewart. The total registration for 1918-1919 was 34. The next session opens Sept. 25, 1919, and ends June 23, 1920.

NEW YORK

New York State, population 10,366,778, has eight medical colleges. Five of these, College of Physicians and Surgeons (Columbia University), Long Island College Hospital, New York Homeopathic Medical College and Flower Hospital, Cornell University Medical College and the University and Bellevue Hospital Medical College are located in New York City, population 5,602,841. Albany Medical College is located in Albany, a city of 110,199 people. The University of Buffalo Medical Department is situated in Buffalo, population 468,558. The College of Medicine, Syracuse University, is in Syracuse, a city of 155,624 inhabitants.

To be eligible to receive a license to practice in New York, students matriculating in 1918-19 and thereafter must have completed two years of college work before entering on the study of medicine. This applies to graduates of 1922 and thereafter.

Albany

ALBANY MEDICAL COLLEGE, 58-64 Eagle Street.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1918 Union University assumed full control. The faculty is composed of 22 professors and 41 instructors, assistants, etc., a total of 63. One year of collegiate work, including college courses in physics, chemistry, biology, English, and French or German, is required for admission. Two years of college work are required for admission. The curriculum covers four years of eight months each. The fees for the four years, respectively, are \$195, \$180, \$165 and \$165. The Dean is Dr. Thomas Ordway. The total registration for 1918-1919 was 66; graduates, 12. The eighty-ninth session begins Sept. 22, 1919, and ends June 9, 1920.

Buffalo

UNIVERSITY OF BUFFALO MEDICAL DEPARTMENT, High Street, near Main.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1887. The faculty is composed of 30 professors and 77 lecturers, assistants, etc., a total of 107. Two years of collegiate work, including college courses in physics, chemistry, biology, English and French or German are required for admission. The course covers four years of eight months each. The total fees for each of the four years are \$200, matriculation fee \$5. The Dean is Dr. C. Sumner Jones. Total registration for 1918-1919 was 183; graduates, 37. The seventy-fourth session begins Sept. 29, 1919, and ends June 11, 1920.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 437 West Fifty-Ninth Street.—Organized in 1807 by the Regents of the University of the State of New York as their medical department. The first class graduated in 1811. In 1860 it became, by affiliation, the Medical Department of Columbia College. It was made a permanent part of Columbia College by legislative enactment in 1891. That institution became Columbia University in 1896. The faculty is composed of 93 professors and 157 instructors, demonstrators, etc., a total of 250. Two years of collegiate work, including courses in physics, chemistry, biology, English and either French or German are required for admission. The course covers four years of eight months each. Continuous sessions adopted for seniors only. The Dean is Dr. Samuel W. Lambert. The total fees for the four years, respectively, are \$265, \$251, \$250 and \$275. Total registration for 1918-1919 was 526; graduates, 138. The one hundred and twelfth session begins Sept. 24, 1919, and ends June 2, 1920.

CORNELL UNIVERSITY MEDICAL COLLEGE, First Avenue and Twenty-Fifth Street, New York City, and Ithaca.—Organized in 1898. The first class was graduated in 1899. The work of the first year may be taken either in Ithaca or New York. The faculty is composed of 47 professors and 87 assistants, lecturers, instructors, etc., a total of 134. All candidates for admission must be graduates of approved colleges or scientific schools or seniors of approved colleges which will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the Bachelor degree on the completion of the year's work. The candidate must also have such knowledge of physics, inorganic chemistry and biology as may be obtained in college by a year's course in these subjects when accompanied by laboratory work. The fees for each of the four years are, respectively, \$340, \$335, \$245 and \$250. The Acting Dean is Dr. Walter I. Niles. Total registration for 1918-1919 was 206; graduates, 29. The twenty-second session begins Sept. 29, 1919, and ends June 10, 1920.

LONG ISLAND COLLEGE HOSPITAL, Henry and Amity Streets, Brooklyn.—Organized in 1858. The first class graduated in 1860. It has a faculty of 20 professors and 108 assistants, instructors, etc., a total of 128. Two years of collegiate work, including college courses in physics, chemistry and biology, are required for admission. The course covers four years of eight months each. Fees: first year, \$255; second year, \$250; third,

\$350, and \$275 for the fourth year. The secretary is Dr. Otto V. Hoffman. Total registration for 1918-1919 was 370; graduates, 53. The sixty-second session begins Sept. 22, 1919, and ends June 2, 1920.

NEW YORK HOMEOPATHIC MEDICAL COLLEGE AND FLOWER HOSPITAL, Eastern Boulevard, between Sixty-Third and Sixty-Fourth Streets.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title, New York Homeopathic Medical College, was assumed in 1869. Present title assumed in 1903. The first class graduated in 1861. The course covers four years of eight months each. It has a faculty of 40 professors and 20 lecturers and assistants. The total fees for the four years, respectively, are \$220, \$210, \$200 and \$230. Total registration for 1918-1919 was 143; graduates, 23. The sixtieth session begins Sept. 25, 1919, and ends June 3, 1920.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE, 325 East Twenty-Sixth Street.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. It is the Medical Department of New York University. First class graduated in 1899. The faculty is composed of 71 professors and 89 instructors, etc., in all 160. The course covers four years of eight months each. Entrance requirements are two years of collegiate work, in addition to a standard four-year high school course, including college courses in physics, chemistry and biology. The fees for each of the four years are, respectively, \$225, \$225, \$215, and \$240. The Dean is Dr. Samuel A. Brown. Total registration for 1918-1919 was 403; graduates, 79. The next session begins Sept. 16, 1919, and ends June 12, 1920.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 307 311 Orange Street.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three-year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Two years of a recognized college course are required for admission. The course covers four years of thirty-five weeks each. The fees are \$320 annually, or tuition fee, \$10. The faculty is composed of 34 professors and 57 associate and assistant professors, lecturers and instructors. The Dean is Dr. John L. Hoffman. The total enrollment for 1918-1919 was 132; graduates, 22. The forty-ninth session begins Sept. 16, 1919, and ends June 9, 1920.

NORTH CAROLINA

North Carolina, population 2,418,550, has two medical schools, each of which gives only the first two years of the medical course. The School of Medicine of the University of North Carolina is located at Chapel Hill, population 1,149. Wake Forest College School of Medicine is at Wake Forest, population 1,443.

To be eligible for a license to practice medicine in North Carolina, graduates of 1918 and 1922 must have completed, respectively, one year and two years of college work including courses in physics, chemistry and biology in addition to 14 units of high school work before beginning the study of medicine.

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Two years of collegiate work are required for admission. The faculty is composed of 42 professors and 12 lecturers and assistants, etc., a total of 54. The fees for each year are \$150. The Dean is Dr. I. H. Manning. The total registration for 1918-1919 was 51. The thirty-fourth session begins Sept. 30, 1919, and ends June 11, 1920.

Wake Forest

WAKE FOREST COLLEGE SCHOOL OF MEDICINE—This school was organized in 1902. The faculty, including the professors of chemistry, physics and biology, numbers 11. Only the first two years of the medical course are offered after the completion of freshman and sophomore college work, and on this combined course the B.S. degree is conferred. Each annual course extends over nine months. The fees for each year aggregate \$115. The Secretary is E. B. Earnshaw. The total registration for 1918-1919 was 65. The eighteenth session begins Sept. 2, 1919, and ends May 28, 1920.

NORTH DAKOTA

North Dakota, population 752,260, has one medical college, the School of Medicine of the University of North Dakota, which is situated at University, a suburb of Grand Forks, a city of 15,332 people. It gives only the first two years of the medical course.

Candidates for license to practice medicine in North Dakota who graduated in 1912 and thereafter, in addition to

a four-year high school education, must have completed two years of work in an approved college of liberal arts including courses in Latin, physics, chemistry, botany and zoology, prior to beginning the study of medicine. Beginning in 1918, every applicant for a license must show evidence of having spent at least one year as an intern in a hospital.

University

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE—Organized in 1905. Offers only the first two years of the medical course. Two years' work in a college of liberal arts is required for admission. The fees are \$50 each year. The faculty consists of 4 professors and 9 instructors, a total of 13. The Dean is Dr. Harley E. French. The total registration for 1918-1919 was 21. The fourteenth session begins Sept. 22, 1919, and ends June 15, 1920.

OHIO

Ohio, population 5,181,220, has five medical colleges. Two of these, the Medical College of the University of Cincinnati and the Eclectic Medical College, are located in Cincinnati, a city of 404,476 inhabitants. Cleveland, population 674,073, contains one medical school, Western Reserve University School of Medicine. Columbus, population 214,878, contains the two departments of the Ohio State University, the College of Medicine and the College of Homeopathic Medicine.

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICINE, Eden Avenue, Cincinnati General Hospital.—Organized in 1909 by the union of the Medical College of Ohio (founded in 1810) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a merger agreement, March 2, 1909, the Miami Medical College also merged into the University, when the title of Ohio Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Two years of college work are required for admission. The faculty consists of 57 professors, 10 associates, assistants, etc., a total of 166. The course covers four years of eight months each. The fees for each of the first three years are \$130 and for the fourth year, \$170. The Dean is Dr. Christian R. Holmes. The total registration for 1918-1919 was 168; graduates, 27. The next session begins Sept. 30, 1919, and ends June 11, 1920.

ECLECTIC MEDICAL COLLEGE, 630 West Sixth Street.—Organized in 1833 at Worthington as the Worthington Medical College. Removed to Cincinnati in 1843. In 1845 it was chartered as the Eclectic Medical Institute. In 1857 the American Medical College, organized in 1839, was merged into it, and in 1859 the Eclectic College of Medicine and Surgery, organized in 1856, was merged into it. In 1910 it assumed its present title. Classes were graduated in 1843 and in all subsequent years, except 1839 to 1843, inclusive. It has a faculty of 26 professors and 10 lecturers and assistants, a total of 36. Two years of college work are required for admission. The course covers four years of eight months each. The total fees for the four years, respectively, are \$130, \$120, \$120 and \$130. The Secretary is Dr. John K. Sandler. Total registration for 1918-1919 was 86; graduates, 28. The next session begins Sept. 11, 1919, and ends May 11, 1920.

Cleveland

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 1353 East Ninth Street.—Organized in 1843 as the Cleveland Medical College. The first class graduated in 1844. It assumed the present title in 1851. In 1910 it absorbed the Cleveland College of Physicians and Surgeons. The faculty includes 17 professors and 93 lecturers, assistants, etc., a total of 110. The curriculum embraces four years of eight and one-half months each. Three years of college work are required for admission. The total fees for each of the four years are, respectively, \$175, \$160, \$154 and \$155. The Dean is Dr. C. A. Hanna. The total registration for 1918-1919 was 180; graduates, 41. The seventy-seventh session begins Oct. 2, 1919, and ends June 17, 1920.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE, 710 North Park Street.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (founded in 1847) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. The faculty consists of 34 professors and 59 lecturers, demonstrators, etc., a total of 93. Two years of collegiate work are required for admission. The course covers four years of eight months each. Tuition fees are \$152 each year. The Dean is Dr. Eugene E. McCampbell. The total registration for 1918-1919 was 111; graduates, 16. The next session begins Sept. 16, 1919, and ends June 15, 1920.

OHIO STATE UNIVERSITY COLLEGE OF HOMEOPATHIC MEDICINE—Organized in 1914, when the property of the Cleveland Polite Medical College of Cleveland was transferred to the Ohio State University. The faculty numbers 13. Two years of college work are required for admission. The students are taught largely in the same classes and by the same teachers as students of the College of Medicine during the first two years. Tuition fees are \$152 each year. The Dean is Dr. Claude A. Burrett. The total registration for 1918-1919 was 36; graduates, 9. The fifth session begins Sept. 16, 1919, and ends June 15, 1920.

OKLAHOMA

Oklahoma, population 2,245,968, has one medical college, the School of Medicine of the University of Oklahoma. The work of the first and second years is given in the academic laboratories at Norman, a city of 3,724 inhabitants. The work of the third and fourth years is given in Oklahoma City, which has a population of 92,943 and which is eighteen miles north of Norman.

To be eligible for license to practice medicine in Oklahoma, all students matriculating in 1914-15 and in 1917-18, in addition to a four-year high school education, must have completed, respectively, one year and two years of work in an approved college of liberal arts, including courses in physics, chemistry, biology and a modern language prior to beginning the study of medicine.

Norman and Oklahoma City

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE.—Organized in 1900. Gave only the first two years of the medical course at Norman until 1910, when a clinical department was established at Oklahoma City. It has a faculty of 50 professors and 14 instructors, a total of 64. Two years of collegiate work are required for admission. The course is four years of nine months each. An optional course of six years is offered for the degree of B.S. and M.D. The total fees for the four years are, respectively, \$61, \$40, \$23 and \$22. The Dean is Dr. Leroy Long, 325 East Fourth Street, Oklahoma City. The total registration for 1918-1919 was 73; graduates, 12. The session begins Sept. 11, 1919, and ends June 8, 1920.

OREGON

Oregon, population 848,866, has one medical college, the University of Oregon Medical School, located in Portland, a city of 295,463 population.

Portland

UNIVERSITY OF OREGON MEDICAL SCHOOL, Lovejoy and Twenty-Third Streets.—Organized in 1887. The first class graduated in 1888. A class graduated each subsequent year except 1898. Became an integral part of the University of Oregon in 1910. The Willamette University Medical Department was merged in 1913. It has a faculty of 17 professors and 95 lecturers, assistants, etc., a total of 112. Entrance requirements are two years of college work or its equivalent. The course is four years of eight months each. The total fees for the four years are, respectively, \$170, \$100, \$161.75 and \$160. The Dean is Dr. K. A. J. Mackenzie. The total registration for 1918-1919 was 66; graduates, 15. The thirty-third session begins Oct. 1, 1919, and ends May 31, 1920.

PENNSYLVANIA

Pennsylvania, population 8,591,029, has six medical colleges. Of these, Philadelphia, having a population of 1,609,518, contains five, as follows: University of Pennsylvania School of Medicine, Jefferson Medical College, Hahnemann Medical College and Hospital, Woman's Medical College of Pennsylvania and Temple University Department of Medicine. The other school, the School of Medicine of the University of Pittsburgh, is situated in Pittsburgh, a city of 579,000.

To be eligible for license to practice medicine in Pennsylvania, students matriculating in the session 1914-15 and thereafter, in addition to a four-year high school education, must have completed a year's work either in an approved college of liberal arts or a preliminary year in the medical college, including college courses in physics, chemistry and biology, before beginning the study of medicine. He must also have completed an internship of at least one year in an approved hospital.

Philadelphia

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, THIRTH NINTH Street and Hamilton Walk.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772-79, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title, School of Medicine of the University of Pennsylvania, was adopted in 1899. It granted the first medical diploma issued in America. In 1909 it took over the Medical-Chirurgical College of Philadelphia to develop it as a graduate school. The faculty consists of 31 professors, associate, adjunct and assistant professors, and 143 lecturers, associates, instructors, etc., a total of 194. The minimum requirements for admission are a standard of four-year high school course or its equivalent, plus two years of work in an approved college of arts and science, including courses in French or German, and in physics, chemistry and general biology or zoology, with appropriate laboratory exercises. The course embraces four years of study of thirty-four weeks each. The total fees for each of the four years are, respectively, \$33, \$210, \$240 and \$244. The Dean is Dr. William Pepper. Total registration for 1918-1919 was 467; graduates, 125. The one hundred and fifty-fourth session begins Sept. 26, 1919, and ends June 16, 1920.

JEFFERSON MEDICAL COLLEGE, Tenth and Walnut Streets.—Organized in 1825 with its present title as the Medical Department of Jefferson College, Cannonburg, Pa. Classes have been graduated annually since 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its own board of trustees. It has a faculty of 26 professors, associate and assistant professors, and 137 associates, lecturers, demonstrators and instructors, a total of 163. Entrance requirements are a completed standard four-year high school or college preparatory course, or the equivalent, and in addition two years of work in an approved college of arts and science amounting to at least 60 semester hours, including specified courses in physics, chemistry and biology, with laboratory work amounting to 8 semester hours each. The course of study covers graded work of four years of eight and a half months each. The tuition is \$240 a year with a matriculation fee of \$5 paid on admission. The Dean is Dr. Ross V. Patterson. The total registration for 1918-1919 was 451; graduates, 142. The ninety-fifth session begins Sept. 22, 1919, and ends June 5, 1920.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Twenty-First and N. College Avenue.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. It has a faculty of 14 professors and 45 assistants, lecturers, etc., in all 59. Entrance requirements are a completed course in a standard secondary school, and in addition two years of collegiate work, including courses in physics, chemistry, biology and two foreign languages, one of which must be French or German. The curriculum covers four years of eight months each. Fees for each of the four years are, respectively, \$198, \$202, \$184 and \$179.50. The Dean is Dr. Martha Tracy. The total registration for 1918-1919 was 66; graduates, 7. The eightieth session begins Oct. 1, 1919, and ends June 16, 1920.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF PHILADELPHIA, 230-24 North Broad Street.—Organized in 1848 as the Homeopathic Medical College of Pennsylvania. In 1869 it united with the Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Entrance requirements are a completed course in a standard secondary school and in addition two years devoted to a college course, including English and either French, German or Spanish, physics, chemistry and biology. It has a faculty of 36 professors and 48 lecturers, instructors, etc., in all 84. The work covers four years of eight and a half months each. Total fees for each of the four years, respectively, are \$205, \$202, \$202 and \$217. The Dean is Dr. William A. Pearson. The total registration for the college year 1918-1919 was 138; graduates, 25. The seventy-second session begins Sept. 29, 1919, and ends May 31, 1920.

THE TEMPLE UNIVERSITY DEPARTMENT OF MEDICINE, Eighteenth and Bannockburn Streets.—Organized in 1901. The first class graduated in 1904. The faculty numbers 97. Two years of college work are required for admission. The fees for each of the four years, respectively, are \$175, \$170, \$160 and \$160. The Dean is Dr. Frank C. Hammond. The total registration for 1918-1919 was 95; graduates, 30. The nineteenth session begins Sept. 22, 1919, and ends June 1, 1920.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard.—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. The faculty is composed of 16 professors and 114 associates, assistants, etc., 130 in all. Entrance requirements are two years of recognized college work, to have included essentially courses in English, chemistry (inorganic and organic), physics, biology and a reading knowledge of French or German, Italian or Spanish. It is possible for students to get the degree of B.S. and M.D. in six years. The course of study for medicine alone is four years of eight and a half months each. The tuition fee is \$350 a year; matriculation fee, \$15; diploma fee, \$5. The Dean is Dr. Thomas S. Arbutnot. The total registration for 1918-1919 was 147; graduates, 29. The thirty-fourth session begins Sept. 29, 1919, and ends June 4, 1920.

SOUTH CAROLINA

South Carolina, population 1,634,340, has one medical college, situated in Charleston, a city of 60,734 people.

Graduates of 1922 (matriculants of 1918-19) and thereafter, to be eligible for license to practice medicine in South Carolina must have completed, in addition to 14 units of high school work, two years in an approved college, including courses in English, physics, chemistry and biology.

Charleston

THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lucas Street.—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1842 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1858. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. It has a faculty of 37 professors and 24 lecturers, instructors, etc., a total of 61. The course covers four years of eight months each. Two years of collegiate work including courses in physics, chemistry, biology and a modern foreign language are required for admission, in addition to a standard high school preparation. The total fees are \$150 for each of the first two years and \$115 for the last two. The Dean is Dr. Robert Wilson, Jr. Total enrollment for 1918-1919 was 66; graduates, 14. The ninety-first session begins Sept. 26, 1919, and ends June 3, 1920.

SOUTH DAKOTA

South Dakota, population 707,740, has one medical college, the University of South Dakota College of Medicine, located at Vermilion, a town of 2,376 people.

To be eligible for license to practice medicine in South Dakota, graduates of 1915 and thereafter must show that they matriculated in and graduated from medical colleges which required at least two years of collegiate work for admission, including courses in physics, chemistry, biology and a modern language. This affects all students who matriculated in the session of 1911-1912 and thereafter.

Vermilion

UNIVERSITY OF SOUTH DAKOTA COLLEGE OF MEDICINE.—Organized in 1907. Offers only the first two years of the medical course. Two years' work in a college of liberal arts are required for admission. The fees are \$60 each year. The faculty numbers 10. The Dean is Christian P. Lommen, B.S. The total registration for 1918-1919 was 19. The thirtieth session begins Sept. 29, 1919, and ends June 21, 1920.

TENNESSEE

Tennessee, population 2,296,316, has four medical colleges. Of these, Vanderbilt University Medical Department and Meharry Medical College are situated in Nashville, a city with a population of 117,057. The College of Medicine of the University of Tennessee and the University of West Tennessee College of Medicine and Surgery are located in Memphis, population 148,995.

To be eligible for a license to practice medicine in Tennessee, students matriculating in the session of 1914-1915 and of 1918-1919 must have completed, respectively, one year of collegiate work, including courses in physics, chemistry, biology and a modern language, in addition to a four-year high school course before entering on the study of medicine.

Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, three buildings, 879 Madison Avenue.—Organized in 1876 at Nashville as Nashville Medical College. First class graduated 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it continued with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. The faculty includes 36 professors and 69 assistants, instructors, etc., a total of 105. Entrance requirements are a completed secondary education plus two years of collegiate work. Students taking the two-year premedical course in Knoxville may secure the B.S. and M.D. degrees. The total fees for the four years, respectively, are \$107, \$101, \$102 and \$127 for home residents of the state, and \$50 more each year for nonresidents. The Dean is Dr. A. H. Wittenberg. Total registration for 1918-1919 was 63; graduates, 20. The next session begins Sept. 29, 1919, and ends June 2, 1920.

UNIVERSITY OF WEST TENNESSEE MEDICAL DEPARTMENT, Colored, 1190 South Phillips Place.—Organized in 1900. The first class graduated in 1904, and a class graduated each subsequent year. It has a faculty of 20. The course covers four years. Two years of college work are required for admission. The fees are \$60 per year; graduation, \$10 extra. The Dean is Dr. M. V. Jenk. Registration for 1918-1919 was 18; graduates, 4. The twentieth session begins Sept. 22, 1919, and ends about May 23, 1920. Official reports indicate that the diploma of this college are not recognized by the licensing boards of Tennessee and thirty-eight other states.

Nashville

VANDERBILT UNIVERSITY SCHOOL OF MEDICINE.—This school was founded in 1874. The first class graduated in 1875. The faculty consists of 39 professors and 42 lecturers, a total of 81. One year of collegiate work is required for admission. The course covers four years of nearly eight and a half months each. The total fees for the four years, respectively, are \$150, \$150, \$150 and \$175. The Dean is Dr. Lucius E. Burch. The total registration for 1918-1919 was 114; graduates, 25. The forty-sixth session begins Sept. 29, 1919, and ends June 9, 1920.

MEHARRY MEDICAL COLLEGE, Colored, 1118 First Avenue, South.—This school was organized in 1876 as the Medical Department of central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1916. The faculty is made up of 12 professors and 12 instructors, demonstrators, etc., 24 in all. The work embraces four years of thirty weeks each. The total fees for each of the first three years are \$87 and for the fourth years \$97. The President is Dr. G. W. Hubbard. Total registration for 1918-1919 was 175; graduates, 41. The forty-fourth session begins Oct. 7, 1919, and ends May 29, 1920.

TEXAS

Texas, population 4,472,494, has two medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 41,863 inhabitants. The Baylor University College of Medicine is located in Dallas, population 124,527.

To be eligible for a license to practice medicine in Texas, students matriculating in the session of 1914-1915 and thereafter must have completed a year of collegiate work, including courses in physics, chemistry, biology and modern language, in addition to a standard four-year high school course, before entering on the study of medicine.

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 720 College Avenue.—Organized in 1900 as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University at Waco. It acquired the charter of Dallas Medical College in 1904. The first class graduated in 1901. The faculty numbers 49. Entrance requirement is one year of college work in addition to a four-year high school education. For the session of 1918-19 and thereafter two years of collegiate work will be required for admission. The course is four years of eight months each. The fees, for each of the four years, respectively, are \$340, \$155, \$155 and \$150. The Dean is Dr. E. H. Carr. Total registration for 1918-1919 was 126; graduates, 22. The twentieth session begins Sept. 29, 1919, and ends May 27, 1920.

Galveston

UNIVERSITY OF TEXAS DEPARTMENT OF MEDICINE, Academy B, between Ninth and Tenth Streets.—Organized in 1891. The first class graduated in 1892. It has a faculty of 20 professors and 15 lecturers and instructors, a total of 38. The curriculum embraces four years of eight months each. The entrance requirement is two years of collegiate work in addition to a four-year high school education. The total fees for the four years, respectively, are \$78, \$48, \$30.50 and \$18. The Dean is Dr. William S. Carter. Total registration for 1918-1919 was 209; graduates, 51. The twentieth session begins Oct. 1, 1919, and ends May 31, 1920.

UTAH

Utah, population 438,974, has one medical college, the School of Medicine of the University of Utah, situated at Salt Lake City, which has 117,399 people.

To be eligible to secure licenses to practice medicine in Utah, students matriculating in and after the session of 1912-1913, in addition to a four-year high school education, must have completed at least one year of collegiate work prior to beginning the study of medicine, this preliminary college work to have included college courses in physics, chemistry and biology.

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE.—Organized in 1906. Gives only first two years of medical course. Each course covers thirty-six weeks. Two years of collegiate work are required for admission. The medical faculty consists of 10 professors and 14 lecturers and assistants, a total of 24. The fees are \$95 each year. The Dean is Dr. Perry G. Snow. Total registration for 1918-1919 was 28. The thirteenth session begins Sept. 29, 1919, and ends June 6, 1920.

VERMONT

Vermont, population 364,322, has one medical school, located at Burlington, a town of 21,432 people.

Students matriculating in and after the sessions 1912-1913 and of 1918-1919 who desire to practice medicine in Vermont must have obtained a preliminary training, respectively, of one year and of two years of collegiate work, in addition to a standard four-year high school education, this additional year's work to include college courses in physics, chemistry and biology.

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park. Organized with complete course in 1822. Class graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1833 and classes were graduated in 1834 and in all subsequent years. The faculty numbers 42. Two years of college work in addition to a four-year high school education are required for admission. The course of study covers four years of nine months each. Continuous session for seniors only. The total fees for each of the first three years are \$145, and \$170 for the fourth year. The Dean is Dr. H. C. Timblum. The total registration for 1918-1919 was 90; graduates, 20. The next session begins Sept. 24, 1919, and ends June 30, 1920.

VIRGINIA

Virginia, population 2,202,522, has two medical colleges, one, the Department of Medicine of the University of Virginia, situated in Charlottesville, population 12,500, and the

Medical College of Virginia at Richmond, population 156,687. Only graduates of medical colleges registered by the Virginia State Board of Medical Examiners are eligible to obtain licenses to practice medicine in this state. Medical colleges to be so registered must require of all students admitted in the session of 1914-1915, completion of at least one year, and in the session of 1917-1918 and thereafter two years of collegiate work, including courses in physics, chemistry, biology and a modern language, preferably German, in addition to a four-year high school education.

Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. It has a faculty of 20 professors and 13 lecturers, instructors, assistants, etc., a total of 33. The requirements for admission are the completion of a four-year high school course, or its equivalent, and two years of college work devoted to English, mathematics, chemistry, physics and biology, and French or German. Continuous session adopted for seniors only. Total fees for each year are \$140, matriculation fee, \$10. The Dean is Dr. Theodore Hough. The total registration for 1918-1919 was 112; graduates, 25. The ninety-first session begins Sept. 18, 1919, and ends June 16, 1920.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Marshall and College Streets.—Organized in 1838 as the Medical Department of Hampden-Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Classes were graduated in 1840 and in all subsequent years. It has a faculty of 42 professors and 90 lecturers, instructors, etc., a total of 132. The requirement for admission is a four-year high school education and in addition two years of collegiate work, including courses in physics, chemistry, biology and French or German. The course embraces four years of eight months each. The total fees for the four years, respectively, are \$199, \$200, \$200 and \$230. The Dean is Dr. Alfred L. Gray. The total registration for 1918-1919 was 123; graduates, 20, including 3 students of the North Carolina Medical College, who were granted degrees by the latter. The ninety-first session begins Sept. 17, 1919, and ends June 3, 1920.

WEST VIRGINIA

West Virginia, population 1,399,320, has one medical college, the School of Medicine of West Virginia University, which offers the first two years of the medical course. It is located at Morgantown, a city of 12,974 population.

Graduates of 1921 (matriculants of 1917-1918) and thereafter, in order to secure licenses to practice medicine in West Virginia, must have completed, in addition to a high school education, one year of collegiate work, including courses in physics, chemistry and biology, before entering on the study of medicine.

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1902, and gives only the first two years of the medical course. Two years of college work are required for admission and the Bachelor's degree will be granted to those who finish the two years in medicine. Session extends through nine months. The faculty numbers 10. Fees: For residents of the state, tuition \$25 each year, matriculation, \$5; for non-residents, tuition, \$40; matriculation fee, \$10. The Dean is Dr. John N. Simpson. The total registration for 1918-1919 was 39. The next session begins Sept. 22, 1919, and ends June 15, 1920.

WISCONSIN

Wisconsin, population 2,513,758, has two medical colleges, the Medical School of the University of Wisconsin, which teaches the first two years of the medical course, and is located at Madison, a city of 30,699 people, and the Marquette University School of Medicine, located at Milwaukee, a city of 436,535 people.

To be eligible for licenses to practice medicine in Wisconsin, students-matriculating in the session of 1915-1916 (graduates of 1919) and thereafter, prior to entering a medical school, must have completed, besides a four-year high school course, two years of collegiate work, including courses in physics, chemistry, biology and a modern language.

Madison

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL.—Organized in 1907, gave only the first two years of the medical course. For matriculation at least two years in a college of arts and science or an equivalent training are required, including two years of Latin, a reading knowledge of French or German, and at least a year's work in physics, chemistry and biology. It has a faculty of 16 professors and 21 lecturers, instructors, etc., a total of 37. Tuition fees: For residents of the state, \$75

each year; for nonresidents, \$199. The Dean is Dr. Charles R. Barden. The registration for 1918-1919 was 118. The twelfth session begins Sept. 29, 1919, and ends June 16, 1920.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, Fourth Street and Reservoir Avenue.—Organized in December, 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. It has a faculty of 51 professors and 36 assistants, instructors, etc., a total of 87. The entrance requirements include, in addition to a four-year high school education, two years of college work, including courses in physics, chemistry, biology and a modern language. The curriculum is for four years of thirty-four weeks each. The total fees for the four years, respectively, are \$220, \$220, \$220 and \$230. The Dean is Dr. Louis E. Jernain. The registration for 1918-1919 was 73; graduates, 13. The eighth session begins Oct. 1, 1919, and ends June 17, 1920.

PHILIPPINE ISLANDS

The Philippine Archipelago, having a population (estimated 1917) of 8,879,999, has two medical colleges, the University of the Philippines College of Medicine and Surgery and the Medical Faculty of the University of St. Thomas. They are located in the city of Manila, which in 1910 had a population of 234,409.

Manila

UNIVERSITY OF THE PHILIPPINES COLLEGE OF MEDICINE AND SURGERY, Manila.—Organized in 1907 as the Philippine Medical School, under the support of the government of the Philippine Islands. Present title in 1910. The faculty includes 34 professors and 40 lecturers, assistants, etc., a total of 74. Two years of collegiate work leading to the degree of Bachelor of Arts are required for admission. The course extends over five years of nine months each with an additional sixth year of intern service. The Dean is Dr. Fernando Calderon. The total registration for 1918-1919 was 155; graduates, 24. The thirteenth session began July 1, 1919, and ends April 4, 1920.

CANADA

The Dominion of Canada has nine medical colleges, all but one of which require a five-year course, including in the first year courses in physics, chemistry and biology. This course is practically equal to that in the colleges of the United States which require one year of college work for admission, including the science courses named. None of the Canadian colleges has a minimum requirement of two years of collegiate work, or its equivalent, preliminary to or as a part of the medical course. The medical school at Edmonton, Alberta, gives only the first two years of the medical course, or three years, including the preliminary science year.

Alberta

UNIVERSITY OF ALBERTA, FACULTY OF MEDICINE, Edmonton.—Organized in 1913. Offers only the first three years of the five-year medical course, including the preliminary science year. The faculty numbers 12. Fees for the first year are \$63; for the second and third years, each \$88. The registrar is Cecil E. Race, B.A. The registration for 1918-1919 was 89. The seventh session begins Sept. 30, 1919, and ends May 13, 1920.

Manitoba

MANITOBA MEDICAL COLLEGE, Winnipeg.—It is the Medical Faculty of the University of Manitoba. Organized in 1883, first class graduated in 1889 and a class graduated each subsequent year. The faculty numbers 60. The total fees for the five years, respectively, are \$175, \$165, \$170, \$160 and \$160. The entire course covers five years, the first year including premedical courses in physics, chemistry and biology. The Dean is Dr. S. Willis Prowse. Total registration for 1918-1919 was 150; graduates, 30. The next session begins Sept. 15, 1919, and ends May 7, 1920.

Nova Scotia

DALHOUSIE UNIVERSITY, FACULTY OF MEDICINE, Halifax, N. S.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Recognized as an examining faculty, separate from the Halifax Medical College in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the University. By an arrangement between Dalhousie University and the Provincial Medical Board of Nova Scotia, the final professional examinations are conducted conjointly by the university and the board, and candidates may qualify at the same time for their academic degrees and the provincial license. First class graduated in 1872. It has a faculty of 35 professors, lecturers and demonstrators. Requires matriculation examination and a graded course of five years, including premedical courses in physics, chemistry and biology. The fees are \$115 for each of the first two years and \$125 for each of the other three. The total registration for 1918-1919 was 113; graduates, 10. The Secretary is Prof. D. Fraser Harris. The next session begins Oct. 1, 1919, and ends May 27, 1920.

Ontario

UNIVERSITY OF TORONTO, FACULTY OF MEDICINE, Toronto.—Organized in 1827 as the Medical Faculty of King's College. Absorbed in 1853. Reestablished in 1857. In 1902 it absorbed Victoria University, Medical Department, and in 1903 absorbed Trinity Medical College. The course of study covers five years of eight months each, the first year including premedical courses in physics, chemistry and biology. It has a faculty of 53 professors and 163 lecturers, associates, etc., a total of 216. The fees are \$150 each year; graduation fee, \$20. The Dean is Dr. C. K. Clarke. The total registration for 1918-1919 was 698; graduates, 56. The next session begins Sept. 30, 1919, and ends May 31, 1920.

QUEEN'S UNIVERSITY, FACULTY OF MEDICINE, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each year subsequently. The faculty was originally a department of the university, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston. In 1892 the school again became an integral part of Queen's University. The faculty includes 26 professors and 20 assistants, instructors, etc., a total of 46. The fees amount to \$125 each year; fee for M.D., C.M. degrees, \$30. The course covers five years of thirty teaching weeks each, the first year including courses in physics, chemistry and biology. The total registration in 1918-1919 was 228; graduates, 61. The Dean is Dr. J. C. Connell. The next session begins Sept. 22, 1919, and ends June 9, 1920.

WESTERN UNIVERSITY, FACULTY OF MEDICINE, London.—Organized in 1827, first class graduated in 1828, and a class graduated each year subsequently. The Faculty of Medicine became an integral part of Western University in 1913. The faculty numbers 53. The course is five years of eight months each, the first year including premedical courses in physics, chemistry and biology. The total fees for the five years, respectively, are \$125, \$120, \$128, \$120 and \$145. The Acting Dean is Dr. Paul S. McKillop. Total registration for 1918-1919 was 92; graduates, 16. The next session begins Oct. 1, 1919, and ends May 30, 1920.

Montreal

MCGILL UNIVERSITY, FACULTY OF MEDICINE.—Founded 1824 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-39 owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop College. The course extends over five years of eight months each, including the preliminary year devoted largely to physics, chemistry and biology. The faculty numbers 138. The total fees for the five years, respectively, are \$174, \$174, \$174, \$174 and \$204. The total registration for 1918-1919 was 471; graduates, 78. The Registrar is Dr. John W. Scane. The next session begins Oct. 1, 1919, and ends May 30, 1920.

MONTREAL SCHOOL OF MEDICINE AND SURGERY, Montreal.—Organized in 1843, incorporated in 1845. In 1901, by act of parliament, the Medical Faculty of Laval University (organized in 1878) was absorbed. Present name assumed in 1911. A class was graduated in 1845 and in each subsequent year. The faculty numbers 80. The course extends over five years, including premedical courses in physics, chemistry and biology. The total fees for the five years, respectively, are \$140, \$118, \$126, \$126 and \$128. The Dean is Dr. L. P. Lachapelle. The total registration for 1918-1919 was 241; graduates, 23. The next session begins Oct. 3, 1919, and ends June 30, 1920.

Quebec

LAVAL UNIVERSITY, FACULTY OF MEDICINE, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 the Medical Department of Laval University; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 35. The fees are \$90 each year. The course extends over five years, the first year including courses in physics, chemistry and biology. The Dean is Dr. Edwin Turcot, Quebec. Total registration for 1918-1919 was 148; graduates, 22.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

The requirements for admission to and graduation from colleges holding membership in this association are 14 units (15 units after Jan. 1, 1920) of high school work and two years (60 semester hours) of college work.

CURRICULUM: The entire course of four years shall consist of not less than 3,600 hours, and shall be grouped in divisions and subdivided into subjects, each division and each subject to be allotted approximately the number of hours and percentages of the whole shown in the following schedule:

DIVISION I.

ANATOMY, 684 HOURS (19%)	Minimum % of 3,600 Hours.
1. Gross anatomy, including chemical or applied anatomy,	100
2. Microscopic anatomy	
3. Embryology	

DIVISION II.

PHYSIOLOGY AND CHEMISTRY, 468 HOURS (13%)	
1. Physiology	80
2. Biochemistry	50

DIVISION III.

PATHOLOGY AND BACTERIOLOGY, 468 HOURS (13%).

1. Pathology, including necropsies	100
2. Bacteriology, including serology and immunology	100
3. Preventive medicine and public health	100

DIVISION IV.

PHARMACOLOGY, 216 HOURS (6%).

1. Materia medica and pharmacy	100
2. Pharmacology	100

DIVISION V.

MEDICINE AND MEDICAL SCIENTIFIC, 1,080 HOURS (30%).

1. General medicine, including laboratory diagnosis	15
2. Pediatrics	4
3. Nervous and mental diseases	30
4. Dermatology and syphilis	2
5. Medical jurisprudence	10

DIVISION VI.

SURGERY AND SURGICAL SPECIALTIES, 675 HOURS (18%).

1. Surgery	11
2. Orthopedic surgery	2
3. Urology	1
4. Ophthalmology	10
5. Otolaryngology and laryngology	10
6. Roentgenology	1

DIVISION VII.

OBSTETRICS AND GYNECOLOGY, 216 HOURS (6%).

1. Obstetrics, including obstetric surgery	4
2. Gynecology	2

When teaching conditions demand it, a student may be transferred from one division to another.

MEDICAL EDUCATION IN THE UNITED STATES

For the nineteenth consecutive year we publish this week statistics dealing with medical education in the United States. The statistics this year show a continuation of the steady improvement since the publishing of the statistics was begun in 1901.

CHANGES OF THE YEAR

The figures show a total enrolment of 13,052 medical students, or 578 less than a year ago. Divided by classes, the total enrolment in the second, third and fourth year classes showed an increase of 661 over the previous year, but this was more than offset by the decrease of 1,179 students in the first year class due largely, if not entirely, to the volunteering or drafting of premedical and freshmen students during 1918. The medical schools had already passed the low ebb in the enrolments resulting from the enforcement of higher entrance requirements, and an increase was expected. The indications are that had it not been for the war, there would have been an increase this year instead of a decrease, in the total enrolment of medical students. The total percentage of students in Class A medical schools was increased during the year from 84.5 to 87.9, whereas, in the Class B schools the percentage was decreased from 10.9 to 8.3, and the percentage in Class C schools was reduced from 4.5 to 3.8.

The total number of graduates this year was 2,656, or only fourteen less than in 1918. The number of graduates from Class A schools, however, increased from 2,024 to 2,220, while the numbers of those graduating from Class B schools decreased from 399 to 268, and from Class C schools from 247 to 168. It is also noteworthy that the number of graduates holding degrees from colleges of arts and sciences increased from 1,024 to 1,180.

The number of medical colleges decreased from ninety to eighty-five, resulting from the closing of two Class A medical schools (one of which was by merger), one Class B institution and two which were rated in Class C. It is encouraging, therefore, that the reductions of the year have been in the number of

students and graduates of the inferior medical colleges, and that the numbers enrolled in the better institutions have been increased.

CHANGES IN FIFTEEN YEARS

The improvements in medical education during the last fifteen years have been remarkable. At the beginning of the campaign for improvement, the United States had more medical schools than all the rest of the world combined, the supply far exceeding the needs of the country. While the number of colleges has been reduced from 162 to eighty-five during the fifteen years, on the other hand, the number enforcing an entrance requirement of two years or more of collegiate work increased from four, or 2.5 per cent. of all colleges, in 1904 to seventy-eight, or 92.9 per cent. of all colleges, in 1919. The number of medical students was decreased from 28,142 to 13,052, but at the same time the number who had higher preliminary qualifications was increased from 1,761, or 6.2 per cent. of all students, in 1904 to 12,570, or 96.3 per cent. of all students, in 1919. While the number of graduates was reduced from 5,747 to 2,656, at the same time the number of graduates who had the better preliminary qualifications was increased from 369, or 6.4 per cent. of all graduates, in 1904 to 2,492, or 94.9 per cent. of all graduates, in 1919. While the annual totals of colleges, students and graduates have been decreased by about 50 per cent., the number of better colleges has been multiplied by eighteen, and the number of better qualified students and graduates has been multiplied by seven.

OTHER IMPROVEMENTS IN MEDICAL EDUCATION

The improvement in regard to admission requirements, however, is merely an index of changes for the better in other respects. Formerly, the majority of schools were of the independent type; now, almost all are integral parts of high grade universities. Formerly, a large majority of the medical schools were dependent solely on students' fees for maintenance; now, practically all are enjoying larger incomes either from state appropriations or from private endowment. In addition, many of the schools have erected new college buildings, have established additional and better equipped laboratories, and have employed a larger number of better trained teachers who devote all their time to teaching and research. Almost all of the colleges have established more intimate relationships with hospitals by which more abundant clinical facilities are provided and better clinical teaching is made possible. Also, in all the schools the courses of instruction are better graded, and better methods of teaching are employed.

COST OF MEDICAL EDUCATION

These improvements have added largely to the cost of medical education. Actual statistics show that the cost of teaching in eighty-two medical schools in 1916

exceeds by about three times the sum obtained from students' fees. At the same time the cost to the medical students in tuition fees has been only moderately advanced. A number of the high grade state university medical schools charge very low fees for residents of the respective states. During the last fifteen years also there have been made available more than 300 scholarships and generous loan funds in thirty-seven of the better medical schools, so that needy but deserving medical students still have abundant opportunities to study medicine. There is certainly no excuse for continuing a low quality of medical education for the sake of "the poor boy" who, by the way, is usually sufficiently acquainted with values to seek the better and not the poorer medical schools.

PROPORTION OF PHYSICIANS TO POPULATION

While there has been a decided reduction in the total numbers of medical students and graduates, we are still far from experiencing a dearth of physicians. That there should be a special demand for physicians during the war was to be expected, and was merely a parallel to the demand for those engaged in other professions or skilled occupations. The temporary scarcity is rapidly disappearing with the return of medical officers to civilian life. That the number of physicians is still fully ample to meet the needs of the country is shown by the fact that there is one physician to every 720 people throughout the United States (compare Table 14, p. 513). That there is a need of physicians in certain rural districts is a problem which will not be met by lowering the standards of medical education—this need has always existed and always will, unless physicians under government employ are assigned to those districts. There is also need of better health officers and better medical skill and advice, but to meet these needs, not greater numbers but better qualified physicians are required.

FURTHER IMPROVEMENTS NEEDED IN MEDICAL EDUCATION

Notwithstanding the great progress in medical education, the world war has emphasized the need of still further improvement. In the immediate future, medical colleges should establish closer relations with teaching hospitals, should secure greater abundance of teaching material and, more particularly, should reorganize their clinical faculties and adopt greatly improved methods of clinical instruction. It is the clinical side which needs most consideration.

The achievements of the past fifteen years seem insignificant when one considers the possibilities for further development in both undergraduate and graduate medical instruction, and the great advances possible in medical research and in public health and disease prevention. The next decade holds promise of great progress in medical education.

BLOOD REGENERATION AND BONE MARROW ACTIVITY

Although the length of life of the red cells of the blood is still unknown, there is no doubt that they undergo disintegration sooner or later. Sometimes their destruction is hastened by disease; sometimes the erythrocytes are lost to the body through hemorrhage. It becomes important at times, therefore, to learn to what extent reparative processes are taking place and whether red cells are being returned to the circulation. Microscopic examination of the blood during rapid regeneration of the erythrocytes reveals the presence of nucleated forms. Nucleated red cells have therefore been taken as "an inevitable feature of rapid blood regeneration." As Macleod¹ has pointed out, however, changes in the mode of red blood cell formation may be responsible for the nucleated forms.

Some time ago Warburg² demonstrated that whereas normal human blood consumes very little oxygen, blood such as that of birds, which contains nucleated erythrocytes, may evince a high oxygen absorption. Morawitz³ has observed, however, that even in mammals blood obtained during the regeneration following an anemia may show an absorption of oxygen that cannot be accounted for by nucleated cells or by substances possibly dissolved in the plasma. The explanation seems now to have been furnished by Harrop⁴ of the Medical Clinic at the Johns Hopkins Hospital, Baltimore. Starting with the assumption that the red cells in the blood which appear reticulated after certain methods of histologic staining are "youthful erythrocytes," Harrop has found that blood which contains abnormal numbers of them has an oxygen absorption proportional to the percentage of reticulated cells present. These two factors are interdependent; according to Harrop, both are due to the presence of abnormal numbers of youthful cells and both are probably rather accurate indicators of functional regeneration in the bone marrow and of the amount of blood regeneration. According to this latest American research, normal mature human erythrocytes have no oxygen consumption measurable by present methods. Furthermore, when it is measurably increased in the blood of individuals with anemia, the oxygen consumption has no direct relation to the severity of this symptom, and no constant relation to histologic abnormalities in the erythrocytes other than increases in the number of reticulated cells. A large proportion of all the nonnucleated red blood cells in the bone marrow are reticulated. Accordingly, the increase in the number of these forms, along with increase in the hemoglobin of the blood and a greater oxygen consumption thereby, is indicative of increased activity of the bone marrow.

EMIL FISCHER

In his biographic study of "Great Men," Ostwald divides scientists into the classical and the romantic types. To the former belong such men as Helmholtz and Faraday, who were characterized in their work by steadily advancing from one firm base to another in logical, systematic manner. Pasteur may perhaps be regarded as a most striking representative of the romantic type, which advances suddenly at the call of visions to brilliant success or, more often, except in the case of the most gifted, to dismal failure. Emil Fischer, whose death we recorded two weeks ago, was distinctly of the classical type. His achievements, while exceedingly brilliant, were in every instance the outcome of work systematically planned and developed, following step by step logical processes to an anticipated conclusion. Rarely, if ever, has any scientist accomplished a series of great tasks with so few deviations from the straight road toward each goal sought. Starting out early in his career (for he became a professor in the University of Munich at the early age of 27) on a campaign against three of the most difficult and most important problems of organic chemistry, he lived to succeed in solving each of them in a manner that leaves no doubt of the permanence of his achievements. Fortunately for medicine, each of these problems was of fundamental importance for biologic chemistry. They were: first, the structure of the purins; second, the structure of the carbohydrates, and third, the nature of the protein molecule. The accomplishment of any one of these tasks would have made Emil Fischer one of the greatest living chemists; but alone he solved all three.

There was nothing sensational or spectacular about these advances, as each came in logical order, built up step by step by rational development of existing knowledge and by sound reasoning. Skill in devising methods was the foundation stone of Fischer's success, coupled with a sound logic and great capacity for analytic reasoning. Working first with the hydrazins and related compounds, he developed methods that later were the key to his work with the sugars, and some features of his work on the compounds of phenylhydrazin with sugar are now familiar to every medical student, and are in daily use in biologic laboratories. This work, done chiefly in 1875 to 1877, was followed by brilliant studies on the rosanilin dyes, after which he turned to the purin work, the results of which were published especially between 1881 and 1895. Not only did these studies explain the structure of the purins, but they led to the development of methods for their synthesis, a matter of much practical importance in the case of such extensively used substances as caffeine and theobromin. The work on the structure of carbohydrates was published mainly between 1883 and 1891, and resulted in explaining

the composition and behavior of this vitally important group of substances, as well as furnishing methods of great practical value for their study and determination. As the producer of barbital and numerous other commonly used compounds, Emil Fischer's work came into especially close relation with medicine; but to physicians he is perhaps best known by his service in establishing the character of the protein molecule as nothing more mysterious or complex than a large aggregation of amino-acids united in a simple and uniform way. This work filled up most of the last twenty years of his life, and crowned his career in a gratifying manner. He was the recipient of about every honor possible for a great scientist, including the Nobel prize in 1902. In his laboratory many American students have worked, and he had always a keen interest in America and American affairs. Although he was one of the numerous German professors who signed the famous declaration, after the armistice he admitted to an American chemist that he had been deceived as to the statements on which this document was based, through his relying on the positive statements made by the German chancellor—statements afterward proved to be false.

THE MEDICAL STUDENT AND THE
DEPARTMENT OF THERAPEUTICS

Times have changed since the day when two hundred students perched in an amphitheater to listen to a series of lectures on the uses of calomel or on the intricacies of incompatibles, both therapeutic and chemical, demanded by a complex polypharmacy. Pharmacology and physiology have demonstrated the absurdity of many of the products of ancient pharmacy, and have substituted reason and experiment for empiricism. Undoubtedly the teaching of today is better than that of two decades ago; but when we take stock of just how the system of today operates, and what its results are, the possibility of improvement is evident.

Elsewhere in this issue, Bastedo¹ points out some of the aims of the ideal course in therapeutics, and rightly lays stress on the selection of teachers from among the practicing physicians of the faculty who can think pharmacologically and physiologically; in other words, those detailed to teach should have acquired a knowledge of the physiologic processes which they propose to modify by therapy. It is equally important, however, that those who teach pharmacology in the pre-therapeutic years should have as a background some knowledge of medicine as the prospective student will meet it in the clinical years of study which he is now preparing to enter. The recoil in methods of teaching therapeutics from ancient empiricism to the newer and better methods of demonstration in the pharmacologic laboratory has perhaps led in some schools to an unde-

¹ Bastedo, W. A.: Suggestions for an Ideal Course in Therapeutics, *THE JOURNAL*, this issue, p. 463.

sirable detachment of thought of the pharmacologist from medicine as a whole. The students, unable to discriminate between essentials and nonessentials, are often sidetracked on lines of thought which, though of scientific interest, are given undue prominence to the exclusion of other more important pharmacologic subjects. The ideal teacher of pharmacology should have not only a medical degree but also a hospital internship or its equivalent in clinical experience. He will then be able to add the living clinical word to his demonstration of the action of digitalis on the frog's heart, which will fix the instruction in the mind of the student more permanently than hours of reading.

As Bastedo remarks, the teachers of physiology and pharmacology have a right to expect that the material of their teaching shall be utilized in the later years. But to be later utilized, this material must be so presented that it will be retained in the memory of the student. His thought is toward the coming clinical years; and a brief, well selected reference here and there which shows the relation of present theory to the future practice will help to fix the subject in his memory and to establish points of contact which, when touched later on in the clinical years, will recall to him the principles of function and therapy of the pharmacologic laboratory.

The plea of physiology and pharmacology for more of the student's time will no doubt meet resistance from other departments whose claims are perhaps as urgent; but there seems to be no question that the time now available can be more effectively utilized by those who have had personal experience in the problems the student will meet.

The betterment of therapeutic teaching of the clinical years will come largely as a part of the general improvement of clinical teaching. The ward walk, and instruction of small groups of students in ward clinics, afford opportunities for the teaching of therapeutics in conjunction with symptomatology and diagnosis; and on successive days the student sees the results of therapy on the patient. Necessarily much of this type of teaching is done by men who have graduated within ten years, and who are likely to have had the advantage of good physiologic and pharmacologic training. Their efforts, however, will fall short of ideal teaching without continued supervision. The small clinic and ward walk have added much to medical teaching, but at the same time have introduced individuality to a degree which sometimes borders on confusion. The machinery of a medical school, no matter how well devised, will not run unattended after being set going at the beginning of the year. Constant supervision by heads of departments, with frequent conferences with all instructors at which the subject matter of teaching, including therapeutics, is discussed, will aid in affording the student the type of instruction to which he is entitled.

Current Comment

PYLORIC SECRETION

Many years ago the Breslan physiologist Heidenhain devised an experimental method of securing specimens of uncontaminated secretion from various parts of the stomach while digestive processes were actually in progress. The technic consisted in isolating portions of the stomach wall as pouches opening through fistulas to the exterior where the juice could be collected. The classic observations made by the aid of this procedure have often been criticized on the ground that they are not strictly comparable with what goes on in the intact stomach, because Heidenhain's surgical method necessitated severance of the nervous connections of the isolated gastric pouches. The most striking finding of the earlier investigations¹ was that, in contrast with the acid juice secreted by the fundic portions of the stomach, the pyloric secretion is alkaline in character. Ivy² has reinvestigated this with the aid of animals having gastric pyloric pouches in which the nerves were still intact. The reported results show the pyloric secretion to be thick and viscid, clear in appearance, and very slightly alkaline in reaction. It has a small content of pepsin. According to Ivy's observations, further, the secretion is more or less continuous, showing no change in rate of flow after meals or the administration of secretory stimulants which are known to act on the peptic and pancreatic glands.

PLANS FOR GRADUATE MEDICAL INSTRUCTION IN THE UNITED STATES

The next great advance in medical education in the United States will be in connection with graduate medical instruction. This will require and mean a closer cooperation of hospitals, medical teaching institutions, laboratories, and public health and charity bureaus in each of our large cities. It means that the material available will be organized, skilled teachers selected and listed, courses arranged, ample finances secured and—most important—a central administrative office provided so that students can obtain the courses they want with the least difficulty and without waste of time. The statement in regard to the New York Association for Medical Education referred to on another page³ will be of interest to all who are concerned in graduate medical work in this country. This association has a board of trustees on which there are representatives of hospitals, laboratories, and medical and postgraduate schools of that city. The commissioners of health and charity and the president of the Bellevue and allied hospitals are ex officio members of that board. Through this organization, all institutions useful in connection with medical education are to be united. A central administrative office has been established, the object being to develop and utilize to the utmost the clinical resources of that city for graduate

medical teaching. A committee on finance is raising funds for immediate needs and planning for larger resources—fifty million dollars is the goal—for the further advancement of the work. A committee on education has in charge educational standards, qualifications of teachers, and the character of courses offered. The employment of a full-time executive secretary adds to the permanence of the movement. Instead of the many agencies acting individually as heretofore, the object sought is to have all cooperate toward securing the best possible results. The plan also contemplates a cordial and extensive cooperation with similar organizations in other countries. Such movements as this should result not only in the improvement of medical education but also in a material benefit to the public. A greater study will be given to the etiology, diagnosis and treatment of individual patients; a greater enthusiasm will result from cooperation; an increased interest in investigation will be developed in all hospitals and on the part of both teachers and students; a greater opportunity for graduate medical study will be within easy reach of American physicians, and the greater knowledge and skill which they obtain will result in a better care of their patients. Furthermore, and not of the least importance, is the very definite fact that, instead of American physicians going to Europe for their postgraduate work, Europeans and South Americans will be coming to the United States.

ILLINOIS' COMMENDABLE CONSOLIDATION OF MEDICAL CHARITIES WITH MEDICAL EDUCATION

When the Illinois Consolidation Law was passed, two years ago, it placed the work of 125 state commissions under nine administrative departments. Under one of the nine, the Department of Public Welfare, were placed the hospitals, charitable and penal institutions of the state, and the department was instructed to conduct research into the causes and treatment of insanity, feeble-mindedness, delinquency, dependency and crime as well as to train physicians, nurses and others for the special work of the department. Its duties, however, were administrative and not educational. To carry out its function, therefore, it was necessary for the department to establish a relationship with some medical teaching institution. As noted on another page,¹ a perpetual agreement was established with another creature of the state, the University of Illinois and its college of medicine. Under this agreement the Department of Public Welfare will secure land and construct buildings for a psychiatric institute, a surgical institute for children, a new eye and ear infirmary, a clinical laboratory, a reconstruction hospital, a contagious disease hospital, a medical school, and other buildings as may be needed. By its approval of this agreement, the Illinois legislature has committed itself to a plan requiring eventually the expenditure of several million dollars. Already it is stated that \$1,500,000 has been appropriated. The old Cubs' ball park just south of the Cook County Hospital has been secured, and the erection of buildings will be begun at

the earliest opportune time. It is intended that these buildings shall be educational in character rather than of the institutional type. This agreement with the University of Illinois College of Medicine will unite with the latter a group of teaching institutions providing almost every kind of clinical material and in any quantity. It will have, therefore, exceptional facilities for medical teaching and research. At the same time the Department of Public Welfare will be fulfilling its obligations to the public by securing through the medical school a corps of trained specialists for the various hospitals and institutions which are, or will be, under its administration.

THE PRESERVATION OF ANTISCORBUTIC FRUIT JUICES

The sensitiveness of the antiscorbutic property of fresh fruits and vegetables toward heat and such methods of food conservation as depend on the use of this agency has been referred to in some detail in THE JOURNAL.¹ It was pointed out that experiments conducted in London give some promise of success in the preservation of the highly valued antiscorbutic fruit juices which have been relied on more than any other food product in the past to prevent scurvy in infants fed on heated milk or special foods, and also in the members of ships' crews or others likely to be kept out of reach of fresh foods for considerable periods. Further substantiation of the development of satisfactory methods of preservation of orange juice has just been recorded in this country by Givens and McClugage² at the University of Rochester. If the process of drying is not conducted at an unduly high temperature and the duration of drying is very short, the desiccated orange juice retains a significant amount of antiscorbutic potency. The latter is diminished as soon as the temperature is raised and the heating prolonged; thus, a temperature of from 55 to 60 C. (131 to 140 F.) for forty hours or more is destructive to the antiscorbutic property. Givens and McClugage, recognizing the need of an antiscorbutic that shall be within the reach of the poorer classes, point out that by desiccation of orange juice it should be possible to save a large amount of fruit product hitherto wasted through the inability to market and sell oranges at the moment that they are ready for sale.

Statistics on Insanity.—On Jan. 1, 1918, there were 239,820 insane patients under treatment in institutions in the United States. Of these, 231,048 were in public institutions, and 8,772 in private hospitals. Compared with the census of Jan. 1, 1917, there was an increase during the year of 6,406 patients in the public institutions and of 541 in the private, a total increase of 6,947. Of the 231,048 patients in public institutions, 207,705 were cared for in state hospitals; 22,443 in county or city institutions, and 900 in institutions for temporary care. The increases during the year in these hospitals were 5,681 and 139, respectively.—*State Hospital Quarterly*, Utica, N. Y., May, 1919.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending August 8, there were 9,661 officers in the Medical Corps, a decrease of 770 from the previous week. The Medical Reserve Corps contained 3,117 officers. The total number of physicians discharged since the beginning of the war is 23,214.

Confirmation of Promotions of Colonels Noble and McCaw

The United States Senate has confirmed the nominations of Col. Walter D. McCaw and Lieut.-Col. Robert E. Noble to be brigadier-generals in the Medical Corps of the United States Army and to serve as assistant surgeon-generals. General McCaw entered the army as an assistant surgeon, Aug. 20, 1884, appointed from the state of Virginia. He holds medical degrees from the Medical College of Virginia and from Columbia University. He was awarded the distinguished service medal for his work in France. He is 59 years old. General Noble entered the service, June 29, 1901, appointed from Alabama. He was graduated from the Alabama Polytechnic Institute, Columbia University and the Army Medical School. He is 49 years old.

New Head for Department of Physical Reconstruction

Major Horace M. Evans, M. C., U. S. Army, has been appointed officer in charge of the section of physical reconstruction in the hospital division, succeeding Col. Frank Billings. The Surgeon-General has also directed the appointment of chiefs of sections of physical reconstruction in the various Army hospitals doing such work. These officers will have charge of all hospital activities pertaining to physical reconstruction of disabled soldiers, acting under the commanding officer with the medical and surgical services.

Medical Supplies for Red Cross

Senator James W. Wadsworth, Jr., chairman of the Senate Military Committee, has introduced a joint resolution to authorize the Medical Department of the Army to turn over to the American Red Cross all surplus medical supplies in France, to relieve the needs of the people of Europe for medical supplies.

Promotion of Dr. Bainbridge to Commander in the Naval Medical Corps

Dr. William Seaman Bainbridge, at present chief of the surgical division of the new 1,200 bed Naval Hospital at Ward's Island, N. Y., and consulting surgeon to the Third Naval District, has been promoted to the rank of commander in class 4, approved July 23. We are informed that this is the first time in the history of the Navy that an official of the reserve force has been promoted to this rank.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST, SUCH AS RELATE TO CITY AFFAIRS, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Sanatorium Sold.—The Highland Park Sanatorium, Montgomery, founded by Dr. Isaac L. Watkins, in 1875, has been sold to Dr. Thomas Brannon Hubbard.

Personal.—Dr. Jacob Roscoe Snyder, Birmingham, has been appointed medical adviser at the Alabama Children's Aid Society. Dr. Fred D. Reynolds has succeeded Dr. E. W. Edahl as assistant state bacteriologist.

Alumni Officers.—At the annual meeting of the Alumni Association of the Medical School of the University of Alabama, Mobile, the following officers were elected: president, Dr. Josiah E. Evans, Mobile; vice presidents, Drs. Abner N. Steele, Anniston, and William W. Perdue, Mobile, and secretary-treasurer, Dr. Eugene Thames, Mobile.

Hospital Notes.—It is announced that the new Coffee Memorial Hospital, Florence, will soon be in operation. The building next door to the hospital will be secured for a nurses' home. A memorial hospital is to be built in Montgomery in honor of soldiers and sailors who served during the world war, and subscriptions for a bond issue of \$50,000 are being secured for construction purposes.

Care of Feeble-minded. The Alabama Society for Mental Hygiene has recently issued a series of news bulletins relative to the increased number of the feeble-minded and insane in that state. At this time there is before the legislature a mental deficiency bill carrying an appropriation for the establishment of the Alabama Home for Mental Inferiors. Many of the bulletins deal with typical instances in which feeble-minded and insane persons have brought great expense to the state.

Health Bill. A bill carrying with it an appropriation of \$150,000 for the furtherance of health work in Alabama, contains the following principal features: adoption of a model law for vital and mortality statistics; adoption of the latest methods of reporting notifiable diseases; a strict social disease control law; regulations on midwifery; prevention of ophthalmia neonatorum; adoption of milk standard; provisions concerning water supply and soil pollution; the inspection of hotels, cafes, barber-shops, meat and milk depots and

dairies; the abolition of part-time health officers; the adoption of an all-time county health officer plan, with the county as a unit, and giving state health officers authority to remove inefficient county health officials.

FLORIDA

Personal.—Dr. Ralph N. Greene, Chattahoochee, has been elected state health officer of Florida, and has entered on his duties. Mr. Joe L. Earnan, West Palm Beach, has been elected president of the state board of health.

Provision for Orthopedic Hospital.—The state health officer announced, July 29, that the state board intended to take advantage of the authority vested in the board and either establish a state orthopedic hospital or employ physicians at various points throughout the state to conduct treatment for the prevention or correction of deformities in children.

GEORGIA

Home for Feeble-minded.—The House of Representatives, July 8, passed by a vote of 140 to 19, the bill providing for a special training school for mental defectives.

Personal.—Dr. Ovid H. Cheek, Dublin, has been appointed health commissioner of Laurens County succeeding Dr. Edward B. Claxton, Dublin, resigned. Dr. John P. Kennedy, Atlanta, has been reelected health officer, and Dr. Claude A. Smith, director of the laboratory of hygiene, of the city of Atlanta.

ILLINOIS

Charge for Telephone Consultation.—Physicians of Kane County announce that hereafter they will charge 50 cents for information given to patients or friends of patients over the telephone.

Infantile Paralysis.—Three new cases of infantile paralysis were reported at Ladd, August 6, and one additional case at Princeton, Peru and East St. Louis, respectively. During the present epidemic there have been seventy-five cases reported, with only two deaths, and the majority of cases were found in LaSalle, Bureau and Putnam counties. The situation is believed to be under control.

Chicago

Physician Fined.—Failure to comply with the state law requirements by reporting a case of sore eyes in a baby is said to have resulted in Dr. Frank J. Zuehlke being fined \$25 and costs, August 5.

Laboratory to Be Enlarged.—In order to increase its capacity for the production of antipneumonia serum, the laboratory of which Dr. Preston Kyes, professor of preventive medicine in the University of Chicago, is in charge, is to be enlarged at a cost of \$5,000.

Infantile Paralysis.—During July, twenty-nine cases of anterior poliomyelitis were reported to the health department, the largest number of cases for July in any year with the exception of 1916. There were, however, only three deaths from the disease during the month.

Graduate Course Lecture.—The ninth lecture of the Graduate Summer Quarter in Medical Science at the University of Illinois, College of Medicine, was delivered, August 6, by Dr. Aaron Arkin, Ph.D., professor of pathology and bacteriology in the University of West Virginia, Morgantown, on "The Influence of Some Chemical Substances on Immunity Reactions."

Nursing Courses.—The Chicago Chapter of the American Red Cross has announced an appropriation of \$15,000 to finance an educational campaign for preparedness against epidemics and civilian diseases. This course is not, as was stated in the last issue of THE JOURNAL, connected in any way with the Nursing School recently opened by the department of health. The lectures in the home nursing course at the old Loyola College are being attended by more than 1,100 women.

MICHIGAN

Personal.—Dr. Harvey E. Hoffman has resigned as city physician of Lansing.

Infant Clinics Opened.—Seven temporary baby clinics operated by the Detroit Board of Health were opened, July 11. These clinics are in addition to the six in board of health centers, and the two in settlement houses at present in operation.

Physician Arrested in Raid.—In a raid made in Detroit, August 31, according to reports, Dr. George A. Fritch, who

has been arrested many times in connection with the performance of illegal operations, was arrested, charged with performing an illegal operation.

Establishment of Health Districts.—Plans have been made to reorganize the department of health activities of Detroit, by dividing the city into ten health districts, each having a full-time physician and a staff of nurses. The new scheme is to be put in operation in Delroy district, in September, with a doctor and sixteen nurses on the staff.

Charges Dismissed.—The charges of violating the medical advertising law and of failing to report a contagious disease, which were pending against Dr. Wilson Fish, Detroit, and the charge of practicing medicine without a license which was pending against Leon Burgess, Detroit, were dismissed, July 31, by Justice Cotter on the request of the department of health.

MINNESOTA

Wassermann Laboratory Established.—The Minnesota State Board of Health opened a Wassermann laboratory, August 1, under the charge of Mr. Ralph M. Sperry, formerly of Philadelphia.

Malpractice Not Proved.—The state supreme court, August 1, decided that Drs. Robert C. Farris and William C. Fortmann, Sherman, could not be held liable for alleged malpractice for the treatment of a child who was suffering from bone disease.

Personal.—Dr. Charles E. Smith, St. Paul, assistant secretary of the state board of health, has been designated as acting executive officer of the board.—Dr. Mabel S. Ulrich, Minneapolis, supervisor of social hygiene education, has just completed a course of lectures on social hygiene, in the summer school of Columbia University.

Sanatorium to Be Closed.—Abandonment of the Ramsey County Tuberculosis Sanatorium at Lake Owasso was approved by the Ramsey County board, July 29, when an item for \$16,826 for the maintenance of the institution was stricken from the budget, at the recommendation of the board of control and at the suggestion of Dr. Arthur B. Ancker, superintendent of the City Hospital.

Bracken's New Work.—Dr. Henry M. Bracken, who was secretary and executive officer of the Minnesota State Board of Health since 1897, but resigned in May to accept a commission as surgeon of the United States Public Health Service, in charge of the War Risk Insurance Medical Service, for the Northwestern states, has opened an office in the Lowry Building, St. Paul.

Venereal Disease Clinics.—During June, 1,235 treatments were administered in the venereal disease clinics under the control of the state board of health, with a total of 526 patients. From Aug. 1, 1918, to the close of the fiscal year, July 1, 1919, 6,770 cases were reported to the division of venereal disease. The division which was formerly located in the capitol at St. Paul is now housed on the university campus in Minneapolis, in the Pathology Building, with the divisions of preventable disease and sanitation. The divisions of records, nursing and vital statistics and the executive officers are in the capitol building in St. Paul.

MISSISSIPPI

Sanatorium Sold.—Dr. Julius Crisler, owner of the Jackson Sanatorium, has disposed of his interest in the hospital to Drs. William W. Smithson and James P. Wall, Jackson.

Society Promotes Propaganda for Care of Feeble-minded.—Under the secretaryship of Dr. Thomas H. Haines, Jackson, the Mississippi Mental Hygiene Commission has issued news bulletins in an endeavor to promote the establishment of a colony for the feeble-minded in Mississippi.

New Hospitals.—The Biloxi City Hospital Association accepted the new hospital, July 19.—A contract has just been let for the erection of a private hospital at Marks. The hospital will be of brick and reinforced concrete construction, will have two wards and about ten private rooms, and will cost about \$20,000.

NEW JERSEY

Hospital Memorial.—Residents of Gloucester will erect a memorial hospital in honor of soldiers of the country who fought in the world war. Decision was reached at a public meeting at the City Hall. It is estimated that the hospital will cost \$50,000. Funds will be raised through an appropriation by the city and by public subscription. The proposed hospital will have twenty-five beds. The annual expense of operation is expected to be \$9,000.

Health Board Quits.—The members and officers of the board of health of National Park resigned in a body in a movement stated to create harmony between the two factions which now exist in the fast growing borough. Mayor Edgar Walters appointed a new board. Council has approved the new appointments and the new board, consisting of William P. Abhill, Charles Chism, Frank Wakeley and E. K. Allen, will likely accept the appointments.

NEW YORK

New York City

New York's Lowest Mortality Record.—For the week ending July 26 a death rate of 8.87 per thousand was recorded, against a rate of 11.21 for the corresponding week of 1918. This is the lowest death rate recorded since the organization of the health department in 1866. The next lowest rate was that of June 21, of this year, which was 9.10 and the third lowest was that for the week of July 19, which was 9.16.

Health Center Opened.—A health center for women and girls has been opened at 43 East Twenty-second Street, under the direction of the social education department of the Young Women's Christian Association. It is under the charge of Dr. Bessie Florence L. Meredith, and the purpose of the center is "to keep well women well." No fees are charged for examination and the center is to be opened from noon to 10 p. m. daily.

New Home for Hospital.—According to a recent announcement, the Beth David Hospital, located at Lexington Avenue and One Hundred and Thirteenth Street, has completed plans to erect a modern seven-story building on the present hospital site. Work on the new building is to begin at once. The building will afford accommodations for 150 patients and will provide increased dispensary facilities. In September, a drive for \$100,000 needed for the new building will be begun.

Personal.—Dr. Simon Flexner of the Rockefeller Institute for Medical Research was elected a fellow of the Royal Society of London, June 26.—Dr. Charles T. Graham-Rogers has been commissioned captain, M. C. N. Y. S. G., and assigned to duty with the Forty-Seventh Infantry.—Dr. Howard Fox has returned from France where he has been in military service and has resumed his practice.—Major James O. Tryon, field director of the American Red Cross at General Hospital No. 41, Fox Hills, Staten Island, has resigned.

The Housing of Addicts.—Following a closed session of the sinking fund commission, and a special meeting of the board of estimate, August 8, Dr. Royal S. Copeland, health commissioner, announced that the proposed home for addicts will be at the Sea View Hospital, Staten Island. The Navy Department will be advised at once of this action which will make unnecessary the turning over of Pelham Bay Naval Station to the city for this purpose which aroused such violent opposition on the part of the residents in that locality. The present action does not bid fair to meet with any greater favor. Ralph McKee, acting president of the Borough of Richmond, has asked Mayor Hylan to postpone the sending of addicts to Seaview Hospital, until a public hearing can be held to thresh out the matter. Protests against the plan are coming in from residents in all parts of Staten Island.

NEBRASKA
